Short-Time Work vs. Lay-off Taxes*

Abstract

While unemployment insurance systems are widely used to insure workers against income losses after separations, it is well known that they can inefficiently increase separations in the labor market. There are two common policy instruments that can counter this known problem: lay-off taxes and short-time work schemes. This study provides a search-and-matching framework to evaluate which of the two is the better policy tool. We show that if only a few firms are financially constrained, lay-off taxes are better because they do not distort working hours in the economy. With a large share of financially constrained firms, short-time work emerges as the superior tool, as lay-off taxes have trouble deterring separations in financially constrained firms. Additionally, short-time work can help provide insurance against income losses to risk-averse workers that constrained firms cannot afford to provide in their wage contracts. Calibrating the model to the U.S economy, we find that short-time work is the superior policy instrument if 27.5% of firms in the economy or more are financially constrained. Finally, we show that combining both instruments can dominate either policy in isolation, with the largest gains arising when both financially constrained and unconstrained firms account for substantial shares of the economy.

1 Introduction

It has long been understood that unemployment insurance systems can inefficiently increase separations in the labor market. To counter this inefficiency, governments commonly have two main policy instruments at their disposal. On the one hand, there are lay-off taxes that, in effect, punish firms for laying off workers. On the other hand, there is the short-time work system that rewards the retention of endangered workers through subsidizing and enabling hours reductions¹.

This raises the natural question, which of the two policy instruments governments should employ. Existing literature highlights that lay-off taxes have many desirable properties. Cahuc and Zylberberg (2008) and Blanchard and Tirole (2008) show that unemployment insurance financed by lay-off taxes can implement the social planner allocation in a canonical implicit contract model. Short-time work, on the other hand, has been shown to have the problem of introducing new inefficiencies into the economy through the distortion of working hours (e.g., Burdett and Wright, 1989; Stiepelmann, 2026). However, these results crucially hinge on the absence of financial constraints for firms. This assumption is widespread in the search and matching literature, but clearly at odds with reality.

In this study, we relax this assumption in a rich yet analytically tractable DMP framework and allow for a share of firms to be financially constrained. Using the Ramsey policy approach, we then determine the welfare consequences of optimally set short-time work benefits and optimally set lay-off taxes.

Our main result is that lay-off taxes are indeed superior when the share of financially constrained firms is small. Short-time work emerges as the superior policy instrument if the share of constrained firms becomes sufficiently large. This is a consequence of two main channels. Firstly, lay-off taxes have trouble deterring separations in financially constrained firms, while short-time work can still operate as effectively as before. Secondly, with financial constraints, firms lose their ability to insure risk-averse workers against negative income shocks. Short-time work can then partially mitigate this and provide insurance against income shocks in the firms' stead.

Quantitatively, after calibrating the model to the U.S. economy, we find that short-time work becomes the superior policy instrument once the share of financially constrained firms reaches 27.5%. While this share is not directly observed, we discuss how existing empirical measures of financial constraints can be interpreted through the lens of the model and find that values of this magnitude are plausible in the U.S. economy.

Finally, we show that combining the two instruments can dominate using either policy in isolation. Because lay-off taxes are most effective at preventing inefficient separations

¹Short-time work systems are pervasive, e.g., in European countries where they were utilized during the Great Recession and the COVID period. Lay-off taxes are implemented, e.g., in the U.S. through an experience-rated unemployment insurance system.

in financially unconstrained firms, while short-time work is most effective in financially constrained firms, the gains from combining them are largest when both types of firms account for substantial shares of the economy.

The backbone of our model is a canonical Diamond-Mortensen-Pissarides type search and matching model (Mortensen and Pissarides, 1993, 1994) with idiosyncratic productivity shocks, endogenous separations, and generalized Nash-Bargaining between workers and firms. We augment the standard model with three realistic key ingredients: Risk aversion on the worker side, financial constraints on the firm side, and flexibly adjustable working hours. Workers and firms are randomly matched, form expectations over their match productivity, and bargain over wages, working hours, and separation productivity thresholds. Productivity shocks are i.i.d. and realize after firms and workers complete bargaining.

The government implements an unemployment insurance system under which unemployed workers are paid lump sum benefits and either a lay-off tax system or a short-time work scheme. Further, it collects taxes on firms to finance the systems.

In the presence of lay-off taxes, firms have to pay lump-sum lay-off taxes once worker and firm separate after productivity falls below the separation threshold. To replicate the U.S. experience-rated unemployment insurance system, we assume that lay-off taxes are backloaded to the next period, thereby avoiding firm bankruptcies.

The short-time work scheme consists of two main components: eligibility conditions and benefit payments. Workers become eligible for short-time work once they agree to reduce their working hours below a threshold specified by the government. Short-time work benefits compensate for lost income by providing fixed payments for each hour not worked relative to normal working hours. Short-time work effectively acts as a subsidy paid directly to workers. Working hours under short-time work are also determined through bargaining between firms and workers. In this setup, firms and workers have an incentive to reduce working hours inefficiently to attract more government support.

We assume that a share of firms is financially constrained. Specifically, we assume that these firms can never borrow more than the expected discounted value of the firm. These constraints have direct welfare implications. With risk-averse workers and risk-neutral firms, firms would like to offer workers insurance against low productivity shocks and commit to paying the worker a fixed (consumption equivalent) wage, no matter how low or high productivity turns out to be. The worker is then willing to accept a slightly lower wage in return for the insurance. This implies that for sufficiently low productivity realizations, firms make ex-post losses. However, if the firm is financially constrained, it cannot make ex-post losses and loses its ability to fully insure workers. Low enough productivity shocks make the borrowing constraint binding, and the shocks pass through to the worker's wage fully. Workers are not committed to staying in the match and quit

once they hit their participation constraint (i.e., once the value from quitting, becoming unemployed, and looking for a new job is greater than staying). Therefore, the welfare effect of financial constraints is twofold: Firstly, firms cannot provide as much insurance to workers as they would like, and secondly, workers quit sooner.

We derive closed-form expressions for optimal lay-off taxes and optimal short-time work schemes, depending on how many firms are financially constrained. The theoretical results show that the sole purpose of lay-off taxes is to offset the fiscal externality of the unemployment insurance system on financially unconstrained firms. However, lay-off taxes cannot correct inefficient separations or address the lack of insurance for workers in financially constrained firms. The intuition is straightforward: once financial constraints become binding, firms can no longer absorb shocks, which are instead passed on to workers in the form of reduced income. Even though firms would like to keep the worker employed to avoid future lay-off taxes, workers quit unitarily when income falls enough, rendering the lay-off tax ineffective².

By contrast, short-time work is particularly effective in supporting financially constrained firms. By supplementing the income of workers who experience reduced hours, it incentivizes workers to remain attached to the firm. In addition, it provides workers with income insurance, where constrained firms can no longer provide it. We proceed to show that short-time work cannot simply be replaced by providing loans to financially constrained firms. This is because where short-time work increases the joint surplus of firms and workers by providing insurance to workers, loans merely shift funds across periods and therefore have no bearing on a worker's wage and her decision to quit. Unlike short-time work, loans therefore do not prevent inefficient separations.

When the share of financially constrained firms is low, lay-off taxes are clearly preferable to short-time work, as the distortionary cost of reduced working hours under short-time work outweighs the cost of insufficient support for financially constrained firms under a lay-off tax regime. However, as the prevalence of financially constrained firms increases, the trade-off shifts. Both theoretically and quantitatively, we demonstrate that short-time work becomes the superior policy instrument once a sufficiently large share of firms face financial constraints. Calibrating the model to the U.S. economy and targeting a 45% unemployment insurance replacement rate, we find that short-time work is the superior policy instrument if 27.5% of firms in the economy or more are financially constrained, which is a realistic figure for the U.S. economy. If the planner is allowed to optimize unemployment insurance benefits jointly with either short-time work or lay-off taxes, this threshold even drops to 24%. We discuss how existing empirical measures of financial constraints can be interpreted through the lens of the model. This evidence suggests that values of this magnitude are plausible in the U.S. economy.

²In the U.S., workers who quit following a substantial deterioration in job conditions remain eligible for unemployment insurance benefits.

Finally, we study the joint design of short-time work and lay-off taxes.³ Because lay-off taxes are most effective at deterring separations among financially unconstrained firms, and short-time work is most suitable for preserving matches at financially constrained firms, their optimal combination can improve upon using either instrument in isolation when sufficiently many firms of both types are present in the economy.

As the share of constrained firms rises, the optimal policy mix shifts from lay-off taxes toward short-time work. We find that the gains from combining the two instruments are largest for intermediate shares of financially constrained firms around 30%.

Related literature We contribute to four branches of the literature. Firstly, we add to the literature about optimal unemployment insurance. The trade-off between the benefits of unemployment insurance and adverse effects on job-search and separations has been a recurring theme in the economic literature (e.g., Shavell and Weiss, 1979; Baily, 1978). How UI should be used optimally has therefore been examined in seminal papers such as Hopenhayn and Nicolini (1997) and Chetty (2006). More recently, Landais et al. (2018) show how UI should vary with labor market tightness, and Kroft and Notowidigdo (2016) show evidence that moral hazard costs of UI are procyclical. We contribute to this literature by evaluating policy tools that can mitigate the adverse externalities of unemployment insurance.

Secondly, there is a branch of the literature that concerns itself with lay-off taxes, often emphasizing their effectiveness in overcoming UI fiscal externalities. Blanchard and Tirole (2008) and Cahuc and Zylberberg (2008) propose frameworks in which lay-off taxes can decentralize the planner solution. Closely related to our work, Jung and Kuester (2015) and Michau (2015) take a Ramsey planner approach and examine optimal unemployment insurance with lay-off taxes and vacancy subsidies in a DMP. Duggan et al. (2023) show that lay-off taxes can act as a stabilizer over the business cycle. Postel-Vinay and Turon (2011), on the other hand, show that employers can use severance packages to coax workers into quitting and avoid lay-off taxes. Ratner (2013) makes the point that the experience-rated UI system in the U.S. reduces lay-offs but also hampers hires. Similarly, Johnston (2021) finds that increases in lay-off taxes lead to less hiring. We contribute to this literature by introducing firm borrowing constraints and showing that they reduce the effectiveness of lay-off taxes.

Thirdly, there is a growing body of research on short-time work, though the literature remains divided on its overall usefulness. Some studies emphasize potential inefficiencies. For example, Burdett and Wright (1989) argue that short-time work encourages inefficient reductions in working hours. Cooper et al. (2017) highlight the risk of subsidizing

³The joint design of the two instruments is of practical relevance. Thirty U.S. states operate short-time compensation programs alongside the experience-rated unemployment insurance system.

employment at unproductive firms, while Giupponi and Landais (2022) raise concerns about impeding beneficial worker reallocations, though they also note that short-time work may support firms in maintaining efficient levels of labor hoarding. Cahuc et al. (2021) raise concern about the potential windfall effects of short-time work.

Other studies focus on the potential advantages of short-time work. Balleer et al. (2016) show that it can introduce valuable flexibility at the intensive margin of employment. Giupponi et al. (2021) argue that short-time work complements unemployment insurance by insuring against different types of labor market shocks. Similarly, Braun and Brügemann (2017) analyze optimal unemployment insurance and short-time work jointly within an implicit contract model.

Despite these recent advancements, the relationship between short-time work and unemployment insurance remains insufficiently understood, as emphasized in a comprehensive review by Cahuc (2024). Addressing this gap, Stiepelmann (2026) introduces the analysis of optimal short-time work policy and optimal unemployment insurance into a search-and-matching framework. Building on this foundation, our paper contributes to this branch of the literature by enhancing the understanding of the interplay between short-time work and unemployment insurance by highlighting the pivotal role of financial constraints.

Finally, there is a literature on firms' financial constraints. Drechsel (2023) argues that earnings-based borrowing constraints react more strongly to shocks. A part of the literature shows that financial constraints matter for monetary shock transmissions (e.g., Ottonello and Winberry, 2020) or innovation (e.g., Cascaldi-Garcia et al., 2023). In the labor market, fewer financial constraints are empirically shown to lead to higher employment (e.g., Campello et al., 2010; Duygan-Bump et al., 2015; Fonseca and Van Doornik, 2022). We contribute to this literature by incorporating financial constraints into a search and matching framework with endogenous employment responses. Unlike Wasmer and Weil (2004) and Iliopoulos et al. (2019), who model hiring costs as working capital so that constraints primarily affect vacancy posting, in our setting financial constraints operate through separations, as constrained firms are less able to sustain unprofitable matches.

2 Model

2.1 Basic Assumptions

Set-Up Time is discrete. There is a unit mass of workers. Workers can be either employed or unemployed. While unemployed, workers search for vacant jobs and receive unemployment benefits b . Unemployed workers and firms with vacancies are matched randomly. The number of contacts is governed by the Cobb-Douglas matching function $m(v, n) = \bar{m} \cdot v^{(1-\gamma)} \cdot (1 - n)^\gamma$, where v is the mass of vacancies and n is the mass of

employed workers. We denote the job-finding rate by f , the vacancy-filling rate by q , and the separation rate by ρ . Let θ denote labor market tightness, i.e. $\theta = \frac{v}{1-n}$.

A worker-firm match produces output y according to the production function

$$y(\epsilon, h) = \epsilon \cdot h^\alpha - (\mu_\epsilon - \epsilon) \cdot k_f$$

where ϵ is realization of a productivity shock $\tilde{\epsilon}$ satisfying $\log \tilde{\epsilon} \sim \mathcal{N}(\mu, \sigma^2)$ with cdf $G(\epsilon)$ and pdf $g(\epsilon)$. New productivity shocks arrive with probability λ . h is the number of working hours worked by the worker, and A is the total factor productivity. The term $(\mu_\epsilon - \epsilon) \cdot k_f$ is a cost shock. While workers are employed they receive a salary $w(\epsilon)$ and suffer disutility $\phi(h) = \frac{h^{(1+\psi)}}{1+\psi}$ from working h hours.

Firm profits go to firm owners of whom there is a mass of ν_f .

Preferences Workers are risk-averse with a concave flow utility function over consumption, net of work disutility $u(c - \phi(h))$. Because utility is defined over consumption-equivalent units, we introduce notation for production in consumption-equivalent units for use in later expressions and let $z(\epsilon, h) = y(\epsilon, h) - \phi(h)$. Firm owners have the same flow utility function u but draw utility only from their consumption c_f (i.e. $u(c_f)$).

Government Policy The government can choose between two policy regimes: the Short-Time Work (STW) regime and the Lay-Off Tax (LT) regime. Since the chosen policy regime has implications for firm and worker value, bargaining, and equilibrium, the remaining model assumptions are described in two separate sections for each respective policy regime in the following.

2.2 The Model with Lay-off Taxes

Government Under the LT regime, firms have to pay lay-off taxes F once the worker and firm jointly agree to separate. In the following, let ρ denote the probability that firms and workers separate. The lay-off tax F and the unemployment insurance benefits b are set by the government. To finance the policy regime, firms pay a lump-sum tax τ whenever their productivity changes. The government budget constraint is

$$n^s \cdot \tau = (1 - n) \cdot b - n^s \cdot \rho \cdot F$$

where n^s is the mass of matches that receive a new productivity shock.

Firms There are two types of firms - financially constrained and financially unconstrained firms. Firms are financially constrained with probability p . When constrained,

once the productivity shock has realized to ϵ , a firm can borrow no more than its expected value, conditional on its realized productivity. Specifically,

$$y(\epsilon, h(\epsilon)) - w^c(\epsilon) \geq -\beta \cdot [\lambda \cdot \bar{J} + (1 - \lambda) \cdot J^c(\epsilon)]$$

must hold. $\bar{J}$ is the expected firm value once a new shock arrives, and $J^c(\epsilon)$ is the value of a constrained firm with productivity draw ϵ . The constrained (monthly) wage function $w^c(\epsilon)$ will be made explicit in the bargaining section below. The bargained-over hours functions will depend on productivity ϵ but not on the financial constraint. Anticipating this, we save on notation and denote $h^u(\epsilon)$ and $h^c(\epsilon)$ as $h(\epsilon)$. Note that with persistent shocks ($\lambda < 1$), a low realization of productivity will lead to a tighter borrowing constraint.

The value of an unconstrained firm *after* productivity realizes to ϵ is

$$J^u(\epsilon) = y(\epsilon, h(\epsilon)) - w^u(\epsilon) + \beta \cdot [\lambda \cdot \bar{J} + (1 - \lambda) J^u(\epsilon)]$$

and the value of a constrained firm *after* productivity realizes to ϵ that is

$$J^c(\epsilon) = y(\epsilon, h(\epsilon)) - w^c(\epsilon) + \beta \cdot [\lambda \cdot \bar{J} + (1 - \lambda) \cdot J^c(\epsilon)]$$

where $\bar{J}$ is the expected firm value *before* the shock has realized and *before* it becomes known if the firm is constrained. It is given by

$$\bar{J} = -\tau + (1 - p) \left(\int_{\epsilon_s^u}^{\infty} J^u(\epsilon) dG(\epsilon) \right) + p \left(\int_{\epsilon_s^c}^{\infty} J^c(\epsilon) dG(\epsilon) \right) - \rho \cdot \beta \cdot F$$

Firms separate from a worker once productivity drops below the separation threshold ϵ_s^u or ϵ_s^c for the unconstrained and constrained case, respectively. We denote the probability of separation when a new shock arrives as ρ . When separation occurs, the firm has to pay a lay-off tax F . In accordance with the experience rating system in the US, we assume that lay-off taxes are backloaded, i.e., they are paid with a one-period delay. This ensures that financial constraints do not bind at the time of separation. The lay-off tax is therefore discounted by β .⁴

Firms can freely enter the labor market and post vacancies at cost k_v . The mass of vacancies v must therefore solve

$$\frac{k_v}{q} = \beta \cdot \bar{J}$$

⁴In principle, a firm could remain financially constrained in the subsequent period and thus be unable to pay the lay-off tax, potentially leading to bankruptcy. We abstract from this possibility and assume that all firms are able to meet their tax obligations when due.

Workers Employed workers can work at financially constrained and unconstrained firms. The value of a worker at an unconstrained firm *after* productivity realizes to ϵ is

$$V^u(\epsilon) = u(w^u(\epsilon) - \phi(h(\epsilon))) + \beta \cdot [\lambda \bar{V} + (1 - \lambda)V^u(\epsilon)]$$

The value of a worker at a constrained firm *after* productivity realizes to ϵ is

$$V^c(\epsilon) = u(w^c(\epsilon) - \phi(h(\epsilon))) + \beta \cdot [\lambda \bar{V} + (1 - \lambda)V^c(\epsilon)]$$

where $\bar{V}$ is the expected worker value *before* a new productivity shock has realized. It is given by

$$\bar{V} = (1 - p) \left(\int_{\epsilon_s^u}^{\infty} V^u(\epsilon) dG(\epsilon) \right) + p \left(\int_{\epsilon_s^c}^{\infty} V^c(\epsilon) dG(\epsilon) \right) + \rho \cdot U$$

With probability ρ , a worker becomes unemployed. The Value of an unemployed worker U is given by

$$U = u(b) + \beta \cdot [f \cdot \bar{V} + (1 - f) \cdot U]$$

Bargaining With financial constraints, bargaining takes place before both the realization of productivity ϵ and whether the firm is constrained or not become known. For each possible state $\epsilon \in \mathbb{R}_+$ worker and firm agree on the total monthly wage functions $w^u(\epsilon)$ and $w^c(\epsilon)$, the hours functions $h^u(\epsilon)$ and $h^c(\epsilon)$, on the separation threshold when unconstrained ϵ_s^u , as well as the separation threshold when constrained ϵ_s^c .

Further, there is no commitment to the contract on the workers' side. This means that if the outside option of the worker becomes weakly better than staying with the match, the worker quits unitarily:

$$V^u(\epsilon) < U, \quad V^c(\epsilon) < U$$

Formally, the bargaining outcome solves

$$\max_{\mathcal{X}} \bar{J}^{1-\eta} (\bar{V} - U)^\eta$$

subject to

$$\begin{aligned} V^u(\epsilon) &\geq U, \quad V^c(\epsilon) \geq U && \text{(commitment problem)} \\ y(\epsilon, h^c(\epsilon)) - w^c(\epsilon) &\geq -\beta [\lambda \bar{J} + (1 - \lambda)J^c(\epsilon)] && \text{(financial constraint)} \end{aligned}$$

where the choice set is given by

$$\mathcal{X} = \{w^u(\epsilon), w^c(\epsilon), h^u(\epsilon), h^c(\epsilon), \epsilon_s^u, \epsilon_s^c\}.$$

where η denotes the bargaining power of workers. Note that firms and workers have to take the commitment problem of the worker and the financial constraints of the firm into account when writing their contracts. Appendix F.1 derives the bargaining outcomes in detail.

Since workers are risk-averse and firms are risk-neutral, the bargaining outcome is that firms insure workers against low-productivity states. Workers will accept a lower average wage in exchange for insurance. As long as the firm is not constrained (either because it is an unconstrained firm or because constraints do not bind) the firm will *fully* insure the worker against productivity risk and the total monthly wage $w(\epsilon)$ will be set to a constant consumption equivalent c^w , equating worker utility across all realizations of ϵ that do not lead to binding constraints. c^w is pinned down by the condition

$$u'(c(\epsilon)) = u'(c^w)$$

Once a firm becomes constrained and the constraint binds, it instead pays the maximum monthly consumption equivalent $c^w(\epsilon)$ it can still afford:

$$c^w(\epsilon) = z(\epsilon) + \lambda \cdot \beta \cdot \bar{J}$$

The hours function that worker and firm agree on is, as already mentioned, the same for constrained and unconstrained firms. It is pinned down by

$$\alpha \cdot \epsilon \cdot h(\epsilon)^{\alpha-1} = h(\epsilon)^\psi$$

both in the constrained and the unconstrained case. The equilibrium, therefore, only contains one general hours Function $h(\epsilon)$. Since $h(\epsilon)$ equates the marginal disutility of work and the marginal product of labor, working hours are always set efficiently.

Note that, because under bargaining, each productivity level ϵ will imply a working hours level $h(\epsilon)$, we write $z(\epsilon, h(\epsilon))$ simply as $z(\epsilon)$. The job-destruction equations pin down the bargained-over separation thresholds of constrained and unconstrained matches:

$$\begin{aligned} z(\epsilon_s^u) + [1 - \beta \cdot (1 - \lambda)] \cdot \beta \cdot F + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + \frac{\lambda - \eta \cdot f}{1 - \eta} \cdot \frac{k_v}{q} &= 0 \\ \frac{u(c^w(\epsilon_s^c)) - u(b)}{u'(c^w)} + (\lambda - f) \cdot \frac{\eta}{1 - \eta} \cdot \frac{k_v}{q} &= 0 \end{aligned}$$

Note that F enters the separation condition for unconstrained firms only. In the un-

constrained case, firms fully insure workers' income against idiosyncratic productivity shocks such that a low idiosyncratic productivity level is not passed on to the worker. As a result, the worker has no incentive to quit unilaterally ($V^u(\epsilon_s^u) \geq U$). The lay-off tax makes separations costly for the firm. It therefore lowers the separation threshold ϵ_s^u . However, a sufficiently low productivity realization in a financially constrained firm causes the constraint to bind, forcing the firm to pass the shock directly through to the worker's income. For low enough productivity levels, the continuation value of employment falls below the worker's outside option, such that $V^c(\epsilon_s^c) \leq U$, and the worker quits unilaterally. Although the firm would prefer to retain the worker in order to avoid paying the backloaded lay-off tax, it lacks the financial resources to offer a wage that satisfies the worker's participation constraint. Consequently, the lay-off tax does not affect the separation decision.

Labor Markets The separation rate ρ is given by $\rho = (1 - p) \cdot \rho^u + p \cdot \rho^c$ where $\rho^u = G(\epsilon_s^u)$ and $\rho^c = G(\epsilon_s^c)$. The steady-state law of motion for employment is

$$n = (1 - \lambda) \cdot n + (1 - \rho) \cdot n^s,$$

where n^s denotes the number of matches that received a new shock

$$n^s = f \cdot (1 - n) + \lambda \cdot n$$

The mass of unemployed workers can be expressed as $u = 1 - n$. The mass of workers who work for unconstrained firms n^u and the mass of workers who work at constrained firms n^c are given by:

$$\begin{aligned} n^u &= \frac{1 - p}{\lambda} \cdot (1 - \rho^u) \cdot n^s \\ n^c &= \frac{p}{\lambda} \cdot (1 - \rho^c) \cdot n^s \end{aligned}$$

Equilibrium A steady state Equilibrium consists of the working hours function $h(\epsilon)$, the consumption equivalent c^w paid as the monthly wage to workers without binding constraints, the consumption-equivalent function $c^w(\epsilon)$ paid when financial constraints bind, the separation thresholds ϵ_s^u and ϵ_s^c , the productivity level at which the borrowing constraint becomes binding ϵ^p and labor market flows, i.e the job-finding rate f , the vacancy-filling rate q and the separation rate ρ^u and ρ^c as well as n . The exact equations pinning down equilibrium and their derivation are delegated to Section F and H in the appendix.

2.3 The Model with Short-Time Work

Government Under the STW regime, firms become eligible for short-time work benefits if they set their working hours on short-time work $h_{\text{stw}}(\epsilon)$ below a threshold D . In this case, the worker receives $s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon))$ worth of benefits. $\bar{h}$ is a parameter that reflects the normal working hour level. In essence, for every hour the worker works less than she would under normal circumstances, she receives compensation s_{stw} . Choosing an hours threshold D is a realistic implementation of what short-time work rules mandate in most economies that have implemented short-time work.⁵ Enforcing working hours reduction can help screen out firms that are actually productive from receiving subsidies because only unproductive firms will find hours reductions optimal (Teichgräber et al., 2022).

In principle, the government chooses the policy parameters D , s_{stw} , and b . However, since the hours functions $h^u(\epsilon)$, $h^c(\epsilon)$, $h_{\text{stw}}^u(\epsilon)$ and $h_{\text{stw}}^c(\epsilon)$ will always be strictly decreasing in ϵ , choosing D is equivalent to setting the eligibility productivity threshold ϵ_{stw} that will induce the same hours threshold D . The resulting government budget constraint is

$$\begin{aligned} n^s \cdot \tau &= \frac{1-p}{\lambda} \cdot n^s \cdot \int_{\epsilon_s^u}^{\max\{\epsilon_{\text{stw}}, \epsilon_s^u\}} s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon)) dG(\epsilon) \\ &\quad + \frac{p}{\lambda} \cdot n^s \cdot \int_{\epsilon_s^c}^{\max\{\epsilon_{\text{stw}}, \epsilon_s^c\}} s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon)) dG(\epsilon) \\ &\quad + (1-n) \cdot b \end{aligned}$$

where n^s is the mass of matches that receive a new productivity shock. ϵ_s^u and ϵ_s^c are the separation thresholds of matches with access to short-time work of unconstrained and constrained matches, respectively. The max operators in the integral limits are necessary because the government can choose an eligibility condition that is so tight that all matches separate without gaining access to short-time work first.

Firms Again, firms can be either financially constrained or unconstrained. With short-time work, they can also currently be on short-time work or not. Firms are financially constrained with probability p . When constrained, once the productivity shock has realized to ϵ , a firm can borrow no more than its expected value, conditional on its realized productivity. Specifically, without access to short-time work

$$y(\epsilon, h(\epsilon)) - w^c(\epsilon) \geq -\beta \cdot [\lambda \cdot \bar{J} + (1-\lambda) \cdot J^c(\epsilon)]$$

⁵In practice, this is implemented as a minimum reduction of hours threshold - which in our model is given by $\frac{D-h}{h}$ and is implicitly chosen by the government through D . Most economies with STW have such a minimum hours reduction condition according to Hijzen and Martin (2013).

and with short-time work

$$y(\epsilon, h_{\text{stw}}(\epsilon)) - w_{\text{stw}}^c(\epsilon) \geq -\beta \cdot [\lambda \cdot \bar{J} + (1 - \lambda) \cdot J_{\text{stw}}^c(\epsilon)]$$

must hold. $\bar{J}$ is the expected firm value once a new shock arrives, and $J^c(\epsilon)$ is the value of a constrained firm without short-time work, and $J_{\text{stw}}^c(\epsilon)$ is the value of a constrained firm on short-time work. The constrained monthly wage function $w^c(\epsilon)$ will be made explicit in the bargaining section below. Like in the model with lay-off taxes, the bargained-over hours functions will depend on productivity ϵ but not on the financial constraint. Anticipating this, we save on notation and denote $h^u(\epsilon)$ and $h^c(\epsilon)$ as $h(\epsilon)$ and $h_{\text{stw}}^u(\epsilon)$ and $h_{\text{stw}}^c(\epsilon)$ as $h_{\text{stw}}(\epsilon)$. Further we write $z(\epsilon)$ instead of $z(\epsilon, h(\epsilon))$ and $z_{\text{stw}}(\epsilon)$ instead of $z(\epsilon, h_{\text{stw}}(\epsilon))$. The value of firm *without* short-time work *after* productivity realizes to ϵ that is unconstrained is

$$J^u(\epsilon) = y(\epsilon, h(\epsilon)) - w^u(\epsilon) + \beta \cdot [\lambda \bar{J} + (1 - \lambda) J^u(\epsilon)]$$

and the value of an unconstrained firm *with* short-time work *after* productivity realizes is

$$J_{\text{stw}}^u(\epsilon) = y(\epsilon, h_{\text{stw}}(\epsilon)) - w_{\text{stw}}^u(\epsilon) + \beta \cdot [\lambda \bar{J} + (1 - \lambda) J_{\text{stw}}^u(\epsilon)] .$$

The value of firm *without* short-time work *after* productivity realizes to ϵ that is constrained is

$$J^c(\epsilon) = y(\epsilon, h(\epsilon)) - w^c(\epsilon) + \beta \cdot [\lambda \bar{J} + (1 - \lambda) J^c(\epsilon)]$$

and the value of a constrained firm *with* short-time work *after* productivity realizes is

$$J_{\text{stw}}^c(\epsilon) = y(\epsilon, h_{\text{stw}}(\epsilon)) - w_{\text{stw}}^c(\epsilon) + \beta \cdot [\lambda \bar{J} + (1 - \lambda) J_{\text{stw}}^c(\epsilon)]$$

where $\bar{J}$ is the expected firm value *before* the shock has realized. It is given by

$$\begin{aligned} \bar{J} = & -\tau + (1 - p) \left(\int_{\max\{\xi_s^u, \epsilon_{\text{stw}}\}}^{\infty} J^u(\epsilon) dG(\epsilon) + \int_{\epsilon_s^u}^{\epsilon_{\max\{\epsilon_s^u, \text{stw}\}}} J_{\text{stw}}^u(\epsilon) dG(\epsilon) \right) \\ & + p \left(\int_{\max\{\xi_s^c, \epsilon_{\text{stw}}\}}^{\infty} J^c(\epsilon) dG(\epsilon) + \int_{\epsilon_s^c}^{\max\{\epsilon_s^c, \epsilon_{\text{stw}}\}} J_{\text{stw}}^c(\epsilon) dG(\epsilon) \right) \end{aligned}$$

The max operators in the integral bounds reflect that a sufficiently strict eligibility threshold ϵ_{stw} can exclude certain matches from accessing short-time work, even if their productivity would allow them to survive with such support but not without it. In this case, otherwise, viable matches are denied access to the short-time work system, leading to

unnecessary separations. Firms can freely enter the labor market and post vacancies at cost k_v . The mass of vacancies v must therefore solve

$$\frac{k_v}{q} = \beta \cdot \bar{J}$$

Workers The value of a worker at an unconstrained firm *without* short-time work *after* productivity realizes to ϵ is

$$V^u(\epsilon) = u(w^u(\epsilon) - \phi(h(\epsilon))) + \beta \cdot [\lambda \bar{V} + (1 - \lambda)V^u(\epsilon)]$$

and the value of a worker at an unconstrained firm *with* short-time work *after* productivity realizes is

$$V_{\text{stw}}^u(\epsilon) = u(w_{\text{stw}}^u(\epsilon) + s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon)) - \phi(h_{\text{stw}}(\epsilon))) + \beta \cdot [\lambda \bar{V} + (1 - \lambda)V_{\text{stw}}^u(\epsilon)]$$

The value of worker *without* short-time work *after* productivity realizes to ϵ who works at a constrained firm is

$$V^c(\epsilon) = u(w^c(\epsilon) - \phi(h(\epsilon))) + \beta \cdot [\lambda \bar{V} + (1 - \lambda)V^c(\epsilon)]$$

and the value of a worker *with* short-time work *after* productivity realizes who works at a constrained firm is

$$V_{\text{stw}}^c(\epsilon) = u(w_{\text{stw}}^c(\epsilon) + s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon)) - \phi(h_{\text{stw}}^c(\epsilon))) + \beta \cdot [\lambda \bar{V} + (1 - \lambda)V_{\text{stw}}^c(\epsilon)]$$

where $\bar{V}$ is the expected worker value *before* a new productivity shock has realized. It is given by

$$\begin{aligned} \bar{V} = & (1 - p) \left(\int_{\max\{\epsilon_{\text{stw}}, \epsilon_s^u\}}^{\infty} V^u(\epsilon) dG(\epsilon) + \int_{\epsilon_s^u}^{\max\{\epsilon_{\text{stw}}, \epsilon_s^u\}} V_{\text{stw}}^u(\epsilon) dG(\epsilon) \right) \\ & + p \left(\int_{\max\{\epsilon_{\text{stw}}, \epsilon_s^c\}}^{\infty} V^c(\epsilon) dG(\epsilon) + \int_{\epsilon_s^c}^{\max\{\epsilon_{\text{stw}}, \epsilon_s^c\}} V_{\text{stw}}^c(\epsilon) dG(\epsilon) \right) \\ & + \rho \cdot U \end{aligned}$$

where ρ is the separation rate. The Value of an unemployed worker U is given by

$$U = u(b) + \beta \cdot [f \cdot \bar{V} + (1 - f) \cdot U]$$

Bargaining Bargaining takes place before both the realization of productivity ϵ and whether the firm is constrained or not become known. With short-time work, there are

a few more items that workers and firms bargain about than in the lay-off tax regime. Further, there is no commitment to the contract on the workers' side. This implies that workers will unilaterally choose to leave the match once the outside option of becoming unemployed offers a higher expected utility than remaining employed at the firm.

$$\begin{aligned} V^u(\epsilon) &< U, & V_{\text{stw}}^u(\epsilon) &< U \\ V^c(\epsilon) &< U, & V_{\text{stw}}^c(\epsilon) &< U \end{aligned}$$

In the case with and without short-time work, respectively. For each possible state $\epsilon \in \mathbb{R}_+$ worker and firm agree on the total monthly wage functions $w^u(\epsilon)$ and $w^c(\epsilon)$, as well as the total monthly wages paid in both cases while on short-time work $w_{\text{stw}}^u(\epsilon)$ and $w_{\text{stw}}^c(\epsilon)$. The hours functions, likewise, are bargained over separately - for times in which the firm has no access to short-time work ($h^u(\epsilon)$ and $h^c(\epsilon)$) and for times on short-time work ($h_{\text{stw}}^u(\epsilon)$ and $h_{\text{stw}}^c(\epsilon)$). Lastly, the separation thresholds are also agreed upon for both cases: access to short-time work and no access to short-time work. We denote the separation thresholds without short-time work by ξ_s^u and ξ_s^c . ϵ_s^u and ϵ_s^c denote the separation thresholds while on short-time work.

Formally, the bargaining outcome solves

$$\max_{\mathcal{X}} \quad \bar{J}^{1-\eta} (\bar{V} - U)^\eta$$

Subject to

$$\begin{aligned} V^u(\epsilon) &\geq U, V^c(\epsilon) \geq U, V_{\text{stw}}^u(\epsilon) \geq U, V_{\text{stw}}^c(\epsilon) \geq U && \text{(commitment problem)} \\ y(\epsilon, h^c(\epsilon)) - w^c(\epsilon) &\geq -\beta [\lambda \bar{J} + (1 - \lambda) J^c(\epsilon)] && \text{(financial constraint)} \\ y(\epsilon, h_{\text{stw}}^c(\epsilon)) - w_{\text{stw}}^c(\epsilon) &\geq -\beta [\lambda \bar{J} + (1 - \lambda) J_{\text{stw}}^c(\epsilon)] && \text{(financial constraint, STW)} \end{aligned}$$

where the choice set is given by

$$\mathcal{X} = \{w^u(\epsilon), w^c(\epsilon), w_{\text{stw}}^u(\epsilon), w_{\text{stw}}^c(\epsilon), h^u(\epsilon), h^c(\epsilon), h_{\text{stw}}^u(\epsilon), h_{\text{stw}}^c(\epsilon), \epsilon_s^u, \epsilon_s^c, \xi_s^u, \xi_s^c\}.$$

Here, η denotes the bargaining power of workers. Firms and workers take both the worker's participation constraints and the firm's financial constraints into account when writing contracts. Appendix G.1 derives the bargaining outcomes.

Since workers are risk-averse and firms are risk-neutral, the bargaining outcome is still that firms insure workers against low-productivity states, while workers will accept a lower average wage in exchange for insurance. Much like in the lay-off tax model, as long as the firm is not constrained (either because it is an unconstrained firm or because constraints do not bind) the firm will *fully* insure the worker against productivity risk

and the total monthly wage $w(\epsilon)$ will be set to a constant consumption equivalent c^w , equating worker utility across all realizations of ϵ that do not lead to binding constraints. This also includes the state where workers are on STW:

$$u'(c^w(\epsilon)) = u'(c_{\text{stw}}^w(\epsilon)) = u'(c^w)$$

Once a firm becomes constrained and the constraint binds, it instead pays the maximum monthly wage $c^w(\epsilon)$ it can still afford. This will depend on whether the firm has access to short-time work or not:

$$\begin{aligned} c^w(\epsilon) &= z(\epsilon) + \lambda \cdot \frac{k_v}{q} \\ c_{\text{stw}}^w(\epsilon) &= z_{\text{stw}}(\epsilon) + s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon)) + \lambda \cdot \frac{k_v}{q}. \end{aligned}$$

When the firm goes on short-time work, the worker is compensated for the reduced working hours by the government. This means that when the firm has a binding borrowing constraint and can only afford to pay the worker $c_{\text{stw}}(\epsilon)$ in monthly wages, going on short-time work can still increase the worker's income. The hours function that worker and firm agree on also differs depending on whether the firm is on short-time work or not. The two cases are pinned down by the conditions

$$\begin{aligned} \alpha \cdot \epsilon \cdot h(\epsilon)^{\alpha-1} &= h(\epsilon)^\psi \\ \alpha \cdot \epsilon \cdot h_{\text{stw}}(\epsilon)^{\alpha-1} &= h_{\text{stw}}(\epsilon)^\psi + s_{\text{stw}}. \end{aligned}$$

Again, the hours functions turn out to be independent of financial constraints and equilibrium; therefore, they only contain the two general hours functions $h(\epsilon)$ and $h_{\text{stw}}(\epsilon)$. Note that without short-time work, the bargaining outcome for working hours equates to the marginal product of labor and the marginal disutility from labor and thus sets working hours efficiently. With short-time work, working hours take the subsidy s_{stw} into account, and hours are set lower than the efficient number of working hours. This means that through inefficiently low working hours, the short-time work scheme introduces a distortion into the economy. The bargained-over separation thresholds are pinned down by the job-destruction equations:

$$\begin{aligned}
z(\xi_s^u) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + \frac{\lambda - \eta f}{1 - \eta} \cdot \frac{k_v}{q} &= 0 \\
z_{\text{stw}}(\epsilon_s^u) + s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^u)) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + \frac{\lambda - \eta f}{1 - \eta} \cdot \frac{k_v}{q} &= 0 \\
\frac{u(c(\xi_s^u)) - u(b)}{u'(c^w)} + (\lambda - f) \frac{\eta}{1 - \eta} \cdot \frac{k_v}{q} &= 0 \\
\frac{u(c_{\text{stw}}(\epsilon_s^c)) - u(b)}{u'(c^w)} + (\lambda - f) \frac{\eta}{1 - \eta} \cdot \frac{k_v}{q} &= 0
\end{aligned}$$

In unconstrained firms, the separation decision is determined as a bargaining outcome: firms and workers separate once their joint surplus becomes negative. Importantly, short-time work benefits are not included in the worker's utility function. The rationale is straightforward—under short-time work, the firm continues to insure the worker's income against idiosyncratic productivity shocks. The worker receives a constant consumption equivalent c^w , regardless of the realization of ϵ . As a result, the worker has no incentive to quit unilaterally.

In constrained firms, the worker's commitment problem can become binding: low productivity realizations are passed through to the worker's income. If income falls sufficiently, the worker chooses to quit. Short-time work increases the worker's available income in such cases, thereby increasing the worker's incentive to remain with the firm. In essence, short-time work operates by reducing the wage burden on the firm required to sustain this consumption level. In effect, short-time work lowers the cost of providing income insurance, thereby reducing the firm's incentive to initiate separations.

Labor Markets The separation rate ρ is given by $\rho = (1 - p) \cdot \rho^u + p \cdot \rho^c$ where $\rho^u = G(\epsilon_s^u) + G(\max\{\xi_s^u, \epsilon_{\text{stw}}\}) - G(\max\{\epsilon_s^u, \epsilon_{\text{stw}}\})$ and $\rho^c = G(\epsilon_s^c) + G(\max\{\xi_s^c, \epsilon_{\text{stw}}\}) - G(\max\{\epsilon_s^c, \epsilon_{\text{stw}}\})$. The remaining worker flows are given by $f = \frac{m}{1-n}$ and $q = \frac{m}{v}$. The steady-state law of motion for employment is

$$n = (1 - \lambda) \cdot n + (1 - \rho) \cdot n^s,$$

where n^s denotes the number of matches that received a new shock

$$n^s = f \cdot (1 - n) + \lambda \cdot n$$

Unemployment can be denoted as $u = 1 - n$. The number of workers who work for unconstrained firms n^u and the number of workers who work at constrained firms n^c are

given by:

$$\begin{aligned} n^u(p) &= \frac{1-p}{\lambda} \cdot (1-\rho^u) \cdot n^s \\ n^c(p) &= \frac{p}{\lambda} \cdot (1-\rho^c) \cdot n^s \end{aligned}$$

Equilibrium A steady state Equilibrium consists of the working hours functions $h(\epsilon)$, $h_{\text{stw}}(\epsilon)$, the consumption equivalent c^w paid as the monthly wage to workers without binding constraints, the consumption-equivalent wage $c^w(\epsilon)$ and c_{stw}^w paid when financial constraints bind, the separation thresholds ξ_s^u , ξ_s^c , ϵ_s^u and ϵ_s^c and labor market flows, i.e the job-finding rate f , the vacancy-filling rate q and the separation rates ρ^u and ρ^c as well as n . The exact equations pinning down equilibrium and their derivation are delegated to Sections G and H in the appendix.

3 Optimal Policy

3.1 The Ramsey Problem

To show the differences in how short-time work and lay-off taxes act against the fiscal externality of UI on separations, we take a Ramsey planner approach. We set up separate Ramsey problems for the lay-off tax regime and the short-time work regime and proceed to compare optimal policies and their implications. In both cases, the Ramsey planner maximizes welfare, subject to the equilibrium constraints stated in Sections F and G in the appendix. To make the theoretical results more concise, we henceforth assume that $\beta \rightarrow 1$ for the remainder of the paper.

To state the welfare function formally, recall that there is a mass of firm owners v^f . Firm owners have the same preferences over consumption as workers and receive equal shares of firm profits in the economy. Further, let Ω denote the *average* loss of production in consumption equivalent units due to hours distortions:

$$\Omega = \frac{1}{1-\rho} \left((1-p) \cdot \underbrace{\int_{\epsilon_s^u}^{\max\{\epsilon_{\text{stw}}, \epsilon_s^u\}} \Omega(\epsilon) dG(\epsilon)}_{:= (1-\rho^u)\Omega^u} + p \cdot \underbrace{\int_{\epsilon_s^c}^{\max\{\epsilon_{\text{stw}}, \epsilon_s^c\}} \Omega(\epsilon) dG(\epsilon)}_{:= (1-\rho^c)\Omega^c} \right)$$

where

$$\Omega(\epsilon) = z(\epsilon) - z_{\text{stw}}(\epsilon).$$

Stiepelmann (2026) shows that $\Omega \geq 0$, $\frac{\partial \Omega}{\partial s_{\text{stw}}} \geq 0$ and $\frac{\partial \Omega}{\partial \epsilon_{\text{stw}}} \geq 0$.

The welfare function is given by

$$W(\pi) = n^u \cdot u(c^w) + n^c \cdot u^c + (1 - n) \cdot u(b) + v^f \cdot u((n \cdot (z - \Omega) - n^u \cdot c^w - n^c \cdot e^c - \tau(b) - \theta \cdot (1 - n) \cdot k_v)/v^f) \quad (1)$$

where n^u is the mass of workers employed at firms that do not hit their constraint and n^c is the mass of workers whose employers have a binding borrowing constraint. u^c is the *average* utility of a worker at a firm that has hit its borrowing constraint. z is the *average* production, net of work-disutility, and Ω is the *average* loss of production in consumption equivalent units due to hours distortions: Under the lay-off tax regime, $\Omega = 0$ will always hold. The *average* total monthly wage of a worker at a firm that has hit its borrowing constraint is e^c . The UI-tax $\tau(b) = (1 - n) \cdot b$ is used to finance the UI system.

π is the vector of policy parameters the planner can choose, i.e., $\pi = (b, F)$ in the lay-off tax regime and $\pi = (b, \epsilon_{\text{stw}}, s_{\text{stw}})$ under the short-time work regime. The problem of the Ramsey planner is given by

$$\max_{\pi} W(\pi) \quad \text{s.t. equilibrium conditions are fulfilled}$$

The full problem is stated in Section H in the appendix. Since the analysis does not focus on distributional effects between firm owners and workers, we set the mass of firm owners ν^f such that the consumption equivalent of workers always equals the consumption of firm owners.

3.2 The Optimal Lay-Off Tax Regime

Before we turn our attention to how F is set optimally, we first look at how the planner sets b in the presence of a lay-off tax. This allows us to illustrate how a lay-off tax interacts with the fiscal externalities caused by unemployment insurance.

Setting the unemployment insurance level b must balance a trade-off. On the one hand, the Ramsey planner would like to insure the risk-averse worker against income losses after a separation. If there were no welfare costs to increasing b , the Ramsey planner would like to set b to a level that fully equates the utility of employed and unemployed workers. However, as is well known, unemployment insurance leads to fiscal externalities.

Increasing b raises the value of unemployment, allowing workers to bargain for higher wages. This increases separations in both financially constrained and unconstrained firms. The resulting decline in firm value in turn reduces vacancy posting. On top of that, the lower continuation value tightens firms' borrowing constraints, further limiting their ability to provide income insurance.

The resulting trade-off between more worker insurance and greater fiscal externalities is balanced by the Ramsey planner's first order condition in proposition 1.

Proposition 1. *The optimal unemployment insurance benefit b given lay-off tax F must fulfill the following first-order condition*

$$\begin{aligned}
\underbrace{(1-n) \cdot \left(\frac{u'(b) - u'(c^w)}{u'(c^w)} \right)}_{\text{Income insurance to unemployed, MUIB}} &= \underbrace{\left(-\frac{df}{db} \right)^{ge} \cdot u \cdot L_v(b)}_{\text{Less vacancy posting, MLV}} + \underbrace{\left(\frac{d\epsilon_s^u}{db} \right)^{ge} \cdot \left(-\frac{\partial n^u(p)}{\partial \epsilon_s^u} \right) \cdot L_s^u(b, F)}_{\text{More separation in unconstrained firms, MLS}^u} \\
&+ \underbrace{\left(\frac{d\xi_s^c}{db} \right)^{ge} \cdot \left(-\frac{\partial n^c(p)}{\partial \epsilon_s^c} \right) \cdot L_{s,\xi}^c(b)}_{\text{More separations in constrained firms, MLS}^c} \\
&+ \underbrace{MIE_b(b)}_{\text{Less income insurance to employed}}
\end{aligned}$$

where L_v denotes the social value of hiring an additional worker, L_s^u and L_s^c denote the social value of the marginal match in an unconstrained and constrained firm,

$$\begin{aligned}
L_v(b) &= \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \bar{J} + \frac{1}{f} \cdot b \right) \\
L_s^u(b, F) &= \lambda \cdot \left(\frac{1}{f} \cdot b - F \right) \\
L_s^c(b) &= \frac{\lambda}{f} \cdot b
\end{aligned}$$

and MIE_b denotes the social costs from the insurance loss in unconstrained firms when UI benefits are set more generously.

$$MIE_b^c(b) = n^c(p) \cdot \frac{1}{1 - \rho^c} \cdot \left(-\left(\frac{d\theta}{db} \right)^{ge} \right) \cdot \left(\int_{\epsilon_s^c}^{\epsilon^p} \lambda \cdot \frac{\gamma}{f} \cdot \frac{u'(c(\epsilon)) - u'(c^w)}{u'(c^w)} dG(\epsilon) \right) \cdot k_v$$

PROOF: See Section I.6 in the appendix.

The term labeled *MUIB* represents the marginal social benefit of a higher unemployment benefits level b , stemming from improved income insurance for unemployed workers.

The term labeled *MLV* captures the marginal social loss associated with a decline in hiring induced by an increase in unemployment insurance benefits. The term comprises two components. First, L_v denotes the social value of hiring one additional worker. Second, $\left(-\frac{df}{db} \right)^{ge} \cdot u$ represents the reduction in the number of new hires. Intuitively, higher unemployment benefits raise the worker's outside option, which puts upward pressure on wages and reduces the value of a worker for the firm. As a result, firms find it less profitable to post vacancies, leading to a decline in job creation.

The MLS terms denote the marginal social loss resulting from increased separations caused by UI benefits. Specifically, MLS^u captures the social cost arising from increased separations in unconstrained firms, while MLS^c captures the corresponding cost in constrained firms. Intuitively, higher unemployment insurance benefits raise workers' outside options, exerting upward pressure on wages. As a result, unconstrained firms want to separate earlier. Additionally, in constrained firms, workers are less willing to accept income reductions and thus quit into unemployment sooner.

The term MLS^u consists of two components. First, L_s^u denotes the social value of the marginal match at an unconstrained firm. Second, $\left(\frac{d\epsilon_s^u}{db}\right)^{ge} \cdot \left(-\frac{\partial n^u(p)}{\partial \epsilon_s^u}\right)$ represents the number of additional separations in unconstrained firms.

Similarly, MLS^c consists of L_s^c , the social value of the marginal match at a constrained firm, and $\left(\frac{d\epsilon_s^c}{db}\right)^{ge} \cdot \left(-\frac{\partial n^c(p)}{\partial \epsilon_s^c}\right)$ which denotes the number of additional constrained matches lost due to higher UI benefits.

Finally, $MIE_b(b)$ denotes the social loss arising from reduced worker income insurance in financially constrained firms. Higher UI benefits lower the firm's continuation value and thereby tighten its financial constraint, limiting its ability to insure workers against adverse shocks.

Note that, in general, all these loss terms consist of the marginal social effect of b on the respective threshold (or labor market tightness in the case of MIE_b^c) multiplied by the mass of affected workers.

The lay-off tax F enters the policy trade-off exclusively through the MLS^u term. Importantly, it does not affect any terms associated with financially *constrained* firms. The intuition is straightforward: once firms become financially constrained, they lose their ability to insure workers against adverse productivity shocks. As described in Section 2, low productivity is then fully passed through to the worker's income. If the income falls sufficiently, the value of remaining employed falls below the value of unemployment ($V^c(\epsilon) < U$) and the worker will choose to quit into unemployment. Since the firm cannot sustain a wage that the worker is willing to work for, it cannot prevent the worker from quitting. Thus, the firm has no way of avoiding paying lay-off taxes, and lay-off taxes have no bearing on the separation decision.

As a result, lay-off taxes can only mitigate the negative fiscal externalities of UI by combating separations in *unconstrained* firms. This means that when $p = 0$, lay-off taxes can act on all separation decisions in the economy. As p increases, the lay-off taxes gradually lose their effectiveness until they lose their bite completely once $p = 1$.

On the upside, the planner can choose to completely eliminate inefficient separations in constrained firms. This can be done with the optimal lay-off tax stated in Proposition 2.

Proposition 2. *The optimal backloaded lay-off tax F is determined by its FOC:*

$$F = T_{UI} \cdot b + BE_t(b) \quad (2)$$

Here, $T_{UI} = \frac{1}{f}$ denotes the expected time a worker spends on the UI system on average.

PROOF: See Section I.5 in the appendix.

The first component captures the fiscal externality of the unemployment insurance system. It reflects the total expected UI benefits a worker receives upon entering unemployment, and thus represents the fiscal cost that each separation imposes on the UI system.

BE_t represents the bargaining effect. The formula reveals that Nash bargaining under risk aversion is not fully efficient: wages cannot perfectly distribute utility between firms and workers. Due to decreasing marginal utility, workers lose more from a wage cut than firms gain. Consequently, wage cuts reduce the joint surplus, leading to fewer vacancies, more separations, and potentially less private insurance.

The bargaining effect captures how lay-off tax increases indirectly affect general equilibrium outcomes through wage adjustments. This same logic applies to the bargaining effects in subsequent formulas analyzing STW, though the mechanism is not repeated each time. Quantitatively, the effect is small, accounting for less than 2 percent of the fiscal externality in case of layoff taxes.

Corollary 1 states that the optimal lay-off tax implements the efficient number of separations in unconstrained firms.

Corollary 1. *(i) Optimal Lay-off taxes fully eliminate socially inefficient separations in unconstrained firms.*

(ii) If $p = 0$, then all inefficient separations are eliminated in the economy

PROOF: See Section I.5 in the appendix.

Note that our model extends the insights of Cahuc and Zylberberg (2008) and Blanchard and Tirole (2008) by embedding optimal lay-off taxes within a modern search-and-matching framework of the labor market. Both of these earlier studies show that lay-off taxes combined with unemployment insurance can decentralize the social planner's allocation in settings that focus solely on the separation margin. By contrast, search-and-matching models feature both a hiring margin and a separation margin. In the absence of financial constraints (i.e., when $p = 0$), our model confirms that the logic underlying lay-off taxes - namely, their ability to correct the fiscal externality associated

with unemployment insurance - carries over to this richer framework by eliminating inefficient separations. Jung and Kuester (2015) show that a combination of a vacancy subsidy, lay-off tax and unemployment insurance can decentralize the planner's solution in a search-and-matching model, as the vacancy subsidy additionally operates on the vacancy-posting margin. Again, their results depend on the assumption that firms do not face financial constraints.

3.3 The Optimal Short-Time Work Regime

Under the short-time work regime the Ramsey planner chooses s_{stw} and ϵ_{stw} (through D). Again, we first turn to how the planner sets the level of UI benefits b in the presence of the short-time work scheme. Setting the unemployment insurance level b must balance the same trade-off as before.

Proposition 3. *The optimal unemployment insurance benefit b given a short-time work scheme $(s_{stw}, \epsilon_{stw})$ must fulfill the following first-order condition:*

$$\begin{aligned}
\underbrace{(1-n) \cdot \left(\frac{u'(b) - u'(c^w)}{u'(c^w)} \right)}_{\text{Income insurance to unemployed, MUIB}} &= \underbrace{\left(-\frac{df}{db} \right)^{ge} \cdot u \cdot L_v(b)}_{\text{Less vacancy posting, MLV}} \\
&+ \underbrace{\left(\frac{d\epsilon_s^u}{db} \right)^{ge} \cdot \left(-\frac{\partial n^u(p)}{\partial \epsilon_s^u} \right) \cdot L_s^u(b, s_{stw})}_{\text{More separations in unconstr. firms, MLS}^u} \\
&+ \underbrace{\mathbb{1}(\epsilon_{stw} \geq \epsilon_s^c) \cdot \left(\frac{d\epsilon_s^c}{db} \right)^{ge} \cdot \left(-\frac{\partial n^c(p)}{\partial \epsilon_s^c} \right) \cdot L_s^c(b, s_{stw})}_{\text{More separations in constr. firms with STW, MLS}_\epsilon^c} \\
&+ \underbrace{\mathbb{1}(\epsilon_{stw} \leq \xi_s^c) \cdot \left(\frac{d\xi_s^c}{db} \right)^{ge} \cdot \left(-\frac{\partial n^c(p)}{\partial \xi_s^c} \right) \cdot L_{s,\xi}^c(b)}_{\text{More separations in constr. firms without STW, MLS}_\xi^c} \\
&+ \underbrace{MIE_b^c}_{\text{Less income insurance to employed workers}}
\end{aligned}$$

where L_v denotes the social value of hiring an additional worker

$$L_v = \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \bar{J} + \frac{1}{f} \cdot b \right)$$

L_s^u, L_s^c and $L_{s,\xi}^c$ denote the social value of a marginal match in a constrained firm, in an unconstrained firm with access to STW, and an unconstrained firm without access to

STW,

$$L_s^i = \left(\frac{\lambda}{f} \cdot b - s_{stw} \cdot (\bar{h} - h_{stw}(\xi_s^i)) \right) \quad \text{with } i \in \{u, c\}, \quad L_{s,\xi}^c = \frac{\lambda}{f} \cdot b$$

and MIE_b^c denotes the total insurance loss from marginally increasing UI benefits in constrained firms

$$\begin{aligned} MIE_b^c = & n^c(p) \cdot \left(-\frac{d\theta}{db} \right)^{ge} \cdot \frac{1}{1 - \rho^c} \cdot \left(\int_{\max\{\epsilon_{stw}, \xi_s^c\}}^{\epsilon^p} \lambda \cdot \frac{\gamma}{f} \cdot \frac{u'(c(\epsilon)) - u'(c^w)}{u'(c^w)} dG(\epsilon) \right. \\ & \left. + \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} \lambda \cdot \frac{\gamma}{f} \cdot \frac{u'(c_{stw}(\epsilon)) - u'(c^w)}{u'(c^w)} dG(\epsilon) \right) \cdot k_v \end{aligned}$$

PROOF: See Section J.6 in the appendix.

As in the lay-off tax regime, the marginal social benefit of more generous unemployment benefits ($MUIB$) must equal the associated marginal welfare losses. These losses arise from three sources: fewer vacancies being posted (MLV), increased separations in both unconstrained and constrained firms (MLS^u and MLS^c), and a loss of insurance in constrained firms (MIE^c). Importantly, constrained firms feature two distinct separation margins. Matches may separate with short-time work (STW) support at the threshold ϵ_s^c , or without STW support at ξ_s^c .

However, there is a key difference between the FOCs under the lay-off tax regime (Proposition 1) and the FOCs under the short-time work regime. The lay-off tax parameter F entered only the MLS^u term, and the lay-off tax could only counteract the adverse effect of unemployment benefits on separations in unconstrained firms. By contrast, the short-time work parameters (s_{stw} , ϵ_{stw}) appear in all the terms except the MLV term. Unlike lay-off taxes, short-time work has an effect not only on separations in unconstrained firms, but can also act on constrained firms, counteracting inefficiently high separations and inefficiently low insurance provision.

The core problem for financially constrained firms is their inability to absorb negative productivity shocks, which forces them to pass the resulting income loss directly onto workers. If the decline in income is large enough, workers may choose to quit. Short-time work functions as a subsidy that partially replaces this lost income, thereby incentivizing workers to remain with the firm. Through this channel, STW not only reduces inefficient separations, captured by the marginal social loss from separations (MLS) terms, but also enhances income insurance by acting on the MIE_b^c term.

A second difference is that the eligibility threshold ϵ_{stw} determines which firms have access to STW, leading to the MLS^c -term being split into two parts. If the eligibility condition is strict, i.e., $\epsilon_{stw} < \xi_s^c$, then some firms that could otherwise survive with

STW support are excluded from the system. Naturally, UI benefits also influence the separation threshold without STW support. Moreover, if ϵ_{stw} is set even more strictly to $\epsilon_{stw} < \epsilon_s^c$, then constrained firms are entirely excluded from the STW system. As a result, unemployment insurance benefits can no longer influence separations under the STW regime, eliminating the corresponding term from the equation.

It is clear from Proposition 3 that short-time work has the advantage of acting on the loss terms of constrained firms. On the downside, as argued in the bargaining paragraph of Section 2.3, firms on short-time work will distort their working hours, in turn leading to welfare losses. The Ramsey planner has to trade off the benefits of short-time work as a tool that can counteract the fiscal externalities of UI in both unconstrained and constrained firms and the adverse effects of hours distortions. This is reflected in how optimal short-time work is set.

We begin by examining how the short-time work eligibility threshold ϵ_{stw} should be determined. The following proposition establishes that there are three candidates for the optimal eligibility threshold. The optimal threshold can be found by comparing the welfare levels induced by these three candidates. As discussed in section 2.3, the optimal eligibility condition in terms of working hours D is uniquely implied by the optimal ϵ_{stw} .

Proposition 4. *Assume that the Ramsey planner never wants to use short-time work to impede vacancy posting by destroying the efficiency of the match.⁶ The optimal eligibility threshold ϵ_{stw}^* is one of three candidates pinned down by the following conditions:*

Candidate 1

Suppose it is optimal to set $\epsilon_{stw} \geq \xi_s^c$ (letting all firms in need access short-time work). If

$$MWL_{\epsilon_{stw}} + BE_{stw,2} > MIE_{\epsilon_{stw}}^c, \quad (3)$$

then the optimal threshold is given by $\epsilon_{stw} = \xi_s^c$.

Otherwise, the optimal threshold solves

$$MWL_{\epsilon_{stw}} + BE_{stw,2} = MIE_{\epsilon_{stw}}^c. \quad (4)$$

Here, $MWL_{\epsilon_{stw}} = n \cdot \frac{\partial \Omega}{\partial \epsilon_{stw}}$ denotes the total welfare loss from marginally increasing STW

⁶In principle, this could happen in extreme cases of deviations from the Hosios condition. In this case, too many vacancies could introduce inefficiencies to such an extent that the Ramsey planner would use short-time work to destroy vacancies. Since this is neither realistic nor the focus of our analysis, we exclude this case. The formal corresponding assumption is stated in Section J.5 in the appendix.

benefits, and $MIE_{\epsilon_{stw}}^c$ denotes the marginal welfare gain from providing income insurance:

$$MIE_{\epsilon_{stw}}^c = n^s \cdot \frac{p}{\lambda} \cdot g(\epsilon_{stw}) \cdot \frac{\frac{u(c_{stw}(\epsilon_{stw})) - u(c(\epsilon_{stw}))}{c_{stw}(\epsilon_{stw}) - c(\epsilon_{stw})} - u'(c^w)}{u'(c^w)} \cdot [c_{stw}(\epsilon_{stw}) - c(\epsilon_{stw})].$$

Candidate 2

Suppose it is optimal to set $\epsilon_{stw} < \epsilon_s^c$ with $\xi_s^u < \epsilon_s^c$ (full exclusion of constrained firms from STW). Then the optimal threshold is given by $\epsilon_{stw} = \xi_s^u$.

Candidate 3

Let $I = [\max\{\epsilon_s^c, \xi_s^u\}, \xi_s^c]$. Suppose it is optimal to set $\epsilon_{stw} \in I$ (partial exclusion of constrained firms in need of STW). If

$$\underbrace{MMS_{\epsilon_{stw}}^c \cdot L_{s,\epsilon}^c(\epsilon_{stw})}_{\text{Social value of preserved matches in constrained firms}} > \underbrace{MWL_{\epsilon_{stw}}^u}_{\text{Social cost of hours distortion in unconstrained firms}} + BE_{stw,2} \quad \forall \epsilon_{stw} \in I, \quad (5)$$

then the optimal threshold is given by $\epsilon_{stw} = \xi_s^c$.

If

$$MMS_{\epsilon_{stw}}^c \cdot L_{s,\epsilon}^c(\epsilon_{stw}) < MWL_{\epsilon_{stw}}^u + BE_{stw,2} \quad \forall \epsilon_{stw} \in I, \quad (6)$$

then the optimal threshold is given by $\epsilon_{stw} = \max\{\epsilon_s^c, \xi_s^u\}$.

Otherwise, the optimal threshold is given by ϵ_{stw} that solves

$$MMS_{\epsilon_{stw}}^c \cdot L_{s,\epsilon}^c(\epsilon_{stw}) = MWL_{\epsilon_{stw}}^u + BE_{stw,2} \quad (7)$$

Here, $L_s^c(\epsilon_{stw})$ denotes the social value of an unconstrained match retained by marginally loosening the participation constraint. $MMS_{\epsilon_{stw}}^c = n^s \cdot \frac{p}{\lambda} \cdot g(\epsilon_{stw})$ denotes the number of constrained matches retained with a looser eligibility condition. $MWL_{\epsilon_{stw}}^u = n^s \cdot \frac{1-p}{\lambda} \cdot \frac{\partial \Omega}{\partial \epsilon_{stw}}$ denotes the additional welfare cost of working hours distortions in unconstrained firms when loosening the eligibility condition. Finally, $BE_{stw,2}$ captures general equilibrium effects through the generalized Nash bargaining process.

PROOF: See Section J.5 in the appendix.

To explain the economic logic behind Proposition 4 and why it can only characterize candidates we first discuss the basic trade-off the Ramsey planner faces. For this, one intuitive additional result is needed, namely that constrained firms will always separate at even higher productivity levels than their unconstrained counterparts as stated by the

following lemma:

Lemma 1. *Constrained firms separate for at higher productivity levels than unconstrained firms:*

$$\epsilon_s^c > \epsilon_s^u \quad \text{and} \quad \xi_s^c > \xi_s^u$$

PROOF: See Section K in the appendix.

This fact confronts the Ramsey planner with the following trade-off: The planner can set the eligibility threshold ϵ_{stw} leniently enough to allow constrained matches that would otherwise separate access to short-time work, that is, $\epsilon_{stw} \geq \xi_s^c$. However, this generates windfall effects: unconstrained matches with productivity $\epsilon \in [\xi_s^u, \epsilon_{stw}]$ also gain access to short-time work, even though they face no separation risk absent the program. These windfall effects are costly because short-time work distorts working hours below their efficient level, reducing aggregate output.

Alternatively, to avoid windfall effects, the planner could choose to ignore constrained firms and set the eligibility threshold to $\epsilon_{stw} = \xi_s^u$. At this threshold, unconstrained firms separate without access to short-time work. In this case, constrained firms with $\epsilon \in [\max\{\epsilon_s^c, \xi_s^u\}, \xi_s^c]$ are excluded from the short-time work system even though they are in greater need of support than unconstrained firms. Since which of these is the lesser evil depends on the exact parameters, Proposition 4 can only characterize candidates for the optimal eligibility threshold.

With this in mind, we now turn to explaining the rationale behind each of the three candidates for the optimal eligibility threshold. One possibility is that the eligibility condition should be set so loosely that all firms in need of support can access short-time work. In this case, candidate 1 is optimal. To provide access to short-time work to all firms in need, $\epsilon_{stw} = \xi_s^c$ is sufficient. The question remains whether an even looser eligibility condition can be optimal. Because short-time work can provide income insurance to workers in financially constrained firms even before the match reaches the separation margin, it may be socially efficient to adopt a more generous eligibility condition. However, this effect could be outweighed by the additional working hours distortion introduced to both constrained and unconstrained firms, in which case the threshold remains at ξ_s^c .

Proposition 4 characterizes the conditions under which either of these cases is optimal. Our numerical results presented in Section 5, indeed, show that quantitatively, the distortion effect dominates and that $\epsilon_{stw} = \xi_s^c$ will be optimal.

A second possibility is to set the eligibility threshold to include only unconstrained firms that are actually in need of short-time work. In this case, candidate 2 is optimal. The

optimal threshold is given by $\epsilon_{stw} = \xi_s^u$. As argued by Stiepelmann (2026) $\epsilon_{stw} < \xi_s^u$ cannot be optimal as this would exclude the most productive firms in need of support from short-time work. Increasing the threshold cannot be optimal either, as this would not impede additional separations but introduce additional distortions in working hours. A third possibility is that the eligibility criterion for short-time work should be set sufficiently strict that some financially constrained firms are excluded, even though STW is necessary to retain their workers, but not strict enough to exclude all financially constrained firms. In this case, candidate 3 is optimal. In this scenario, all unconstrained firms that require STW for worker retention can participate in short-time work, along with some that could survive without it. The Ramsey planner must balance the social gains from protecting constrained firms through a looser eligibility threshold against the costs of windfall effects, the additional hours distortions imposed on unconstrained firms where STW is not needed to retain workers. This trade-off is captured by inequalities 5 and 6 and depends on the value of p .

A higher p increases the share of workers in financially constrained firms. When p is large, the social value of retaining these workers dominates the costs of distorting hours in unconstrained firms, as the marginal cost of hours distortion in unconstrained firms $MWL_{\epsilon_{stw}}^u$ declines with p while the number of constrained firms retained $MMS_{\epsilon_{stw}}^c$ rises. In this case, the eligibility threshold is set sufficiently loose to allow all unconstrained firms for which STW is needed to retain workers to participate, i.e., $\epsilon_{stw} = \xi_s^c$. Conversely, when p is small, hours distortion costs dominate, and the planner effectively ignores STW, setting $\epsilon_{stw} = \xi_s^u$. For intermediate values of p , the optimal threshold might balance the social benefits of worker retention against the social costs of hours distortions in unconstrained firms. Our numerical results in section 5 show that either the social value of worker retention or the social cost of working hours distortion dominate for almost all values of p .

Next, we turn to the optimal level of STW benefits s_{stw} , characterized by the following proposition:

Proposition 5. *The optimal short-time work subsidy s_{stw} is pinned down by the first order condition*

$$\bar{s}_{stw} = \underbrace{\frac{T_{UI}}{T_{STW}} \cdot b}_{\text{Fiscal Ext.}} + \underbrace{\frac{MIE_{s_{stw}}^c}{MMS_{s_{stw}}}}_{\text{Insurance}} - \underbrace{\frac{MWL_{s_{stw}}}{MMS_{s_{stw}}}}_{\text{Distortion}} + \underbrace{BE_{stw,3}}_{\text{Bargaining Effect}}$$

Here, $T_{UI} = \frac{1}{f}$ denotes the expected duration that a worker spends on the UI system, $T_{STW} = \frac{1}{\lambda}$ denotes the expected duration that a workers spends on the STW system, $MIE_{s_{stw}}^c$ denotes the marginal welfare gain from increasing insurance provided to workers

in unconstrained firms:

$$MIE_{stw}^c = \frac{n^c(p)}{1 - \rho^c} \cdot \int_{\epsilon_s^c}^{\max\{\epsilon_s^c, \epsilon_{stw}\}} \left(\frac{u'(c_{stw}(\epsilon)) - u'(c^w)}{u'(c^w)} \right) (\bar{h} - h_{stw}(\epsilon)) dG(\epsilon)$$

Further, $MWL_{\epsilon_{stw}} = n \cdot \frac{\partial \Omega}{\partial \epsilon_{stw}}$ denotes the marginal welfare loss from hours distortion from increasing STW benefits. $MMS_{stw} = MMS_{stw}^c + MMS_{stw}^u$ denotes the marginal number of matches saved with an increase of STW benefits, where

$$\begin{aligned} MMS_{stw}^u &= n^s \cdot \frac{1 - p}{\lambda} \cdot g(\epsilon_s^u) \cdot \frac{\partial \epsilon_s^u}{\partial s_{stw}} \\ MMS_{stw}^c &= \mathbb{1}\{\epsilon_{stw} \geq \epsilon_s^c\} \cdot n^s \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \frac{\partial \epsilon_s^c}{\partial s_{stw}} \end{aligned}$$

denote the marginal number of matches saved in constrained and unconstrained firms. The net-transfer of firms and workers is weighted by how many matches of constrained and unconstrained firms can be retained with an increase in STW benefits:

$$\bar{s}_{stw} = \frac{MMS_{stw}^u}{MMS_{stw}} \cdot s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u)) + \frac{MMS_{stw}^c}{MMS_{stw}} \cdot s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^c))$$

PROOF: See Section J.4 in the appendix.

Proposition 5 highlights both the forces that make more generous short-time work attractive to the Ramsey planner and the associated social costs. The most important motive is the fiscal externality correction arising from the unemployment insurance system. Short-time work helps internalize the fiscal externality that UI imposes on separation decisions in both constrained and unconstrained firms. In unconstrained firms, STW reduces inefficient separations by lowering the cost of insuring workers when the match is hit by a low-productivity shock. In financially constrained firms, STW partly compensates workers for the associated income loss and thereby reduces their incentive to quit.

The optimal level of STW benefits depends on the expected duration of time T_{stw} spent in the STW and UI systems. If the time a match spends in STW T_{stw} is relatively long, the Ramsey planner sets lower benefits in order to encourage reallocation toward more productive matches. Conversely, if workers tend to spend a long time in the UI system, higher STW benefits become desirable, as preserving the match and waiting for the firm's recovery may restore productivity.

The second term reflects the insurance motive for short-time work. It shows that short-time work can provide income insurance to workers in financially constrained firms. Here, MIE_{stw}^c denotes the marginal insurance effect—the total welfare gain from increasing income insurance through higher STW benefits. As in the standard optimal UI framework, the planner would ideally like to fully insure workers against income shocks.

However, the Ramsey planner faces a trade-off: increasing short-time work benefits improves insurance but simultaneously weakens separation incentives. This can be a problem because with full insurance, labor does not get reallocated even for very low levels of productivity, which is inefficient. The optimal level of short-time work benefits therefore balances the insurance motive against the behavioral distortion arising from inefficient worker retention. This trade-off is reflected in the formula by the fact that $MIE_{s_{\text{stw}}}^c$ is scaled by the marginal number of matches preserved when short-time work benefits increase $MMS_{s_{\text{stw}}}$. If short-time work is highly effective at preventing separations, providing insurance through short-time work becomes more distortionary, since higher benefits lead to a larger increase in inefficient retention. In this case, the optimal level of short-time work benefits is lower.

The main reason why the planner does not want to set short-time work benefits too high is that short-time work distorts firms' working hours choices, generating a marginal welfare loss captured by the $MWL_{s_{\text{stw}}}$ term. Since the planner trades off the employment stabilization benefits of worker retention against the efficiency costs from distorted hours, the marginal welfare loss $MWL_{s_{\text{stw}}}$ is scaled by the marginal number of matches preserved, $MMS_{s_{\text{stw}}}$.

It is noteworthy how the Ramsey planner sets the *average net* subsidy $\bar{s}_{\text{stw}}$ optimally and then adjusts the actual benefits s_{stw} to achieve this optimal level. Since constrained firms have higher separation thresholds ($\epsilon_s^c > \epsilon_s^u$), it will hold that financially constrained firms reduce working hours less and get a smaller net subsidy: $s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^c)) < s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^u))$. The net subsidies are weighted according to how many firms of each firm type the Ramsey planner can save with an increase of short-time work benefits ($MMS_{s_{\text{stw}}}^i$). Therefore, optimal short-time work benefits depend on the share of financially constrained firms. As constrained firms receive a smaller net subsidy, an increase in their share requires higher benefits to compensate for the smaller reduction in working hours. At the same time, a higher fraction of constrained firms raises the marginal insurance gain $MIE_{s_{\text{stw}}}^c$, further increasing optimal benefits.

3.4 Why Loans Cannot Replace Short-Time Work

The theoretical analysis shows that short-time work does particularly well when a lot of firms are financially constrained. A common critique of using short-time work to address inefficiencies arising from financial constraints is that such constraints could instead be alleviated by providing loans to firms or workers. However, the financial friction we consider cannot be resolved through the provision of loans.

In our model, the financial friction arises from the assumption that financially constrained firms cannot write fully state-contingent contracts that insure them against

low-productivity realizations. Therefore, in low-productivity states, firms do not have the resources to pay workers enough to sustain the match. However, a Ramsey planner would prefer to retain some of these matches, as workers may inefficiently quit in order to receive UI benefits. Providing loans does not resolve this inefficiency because loans merely shift funds across periods and therefore do not alter the fundamental surplus generated by the match and thus the financial constraint.

To see this, assume the government offers a loan to the firm. For simplicity, assume that the government loans a sum of L to the worker, who has to be repaid if the firm gets productive in the next period and that does not have to be repaid if it is not productive. We assume that the loan is fairly priced so that

$$L = \beta \cdot \lambda \cdot R \cdot L + \beta \cdot 0 \Leftrightarrow R = \frac{1}{\beta \cdot \lambda}.$$

Consider the impact of the loan on the financial constraint:

$$y(\epsilon, h(\epsilon)) + L - w^c(\epsilon) \geq -\beta \cdot [\lambda \cdot (\bar{J} - R \cdot L) + (1 - \lambda) \cdot J^c(\epsilon)]$$

Inserting the fairly priced loan into the formula shows that loans do not alter the financial constraint:

$$y(\epsilon, h(\epsilon)) + L - w^c(\epsilon) \geq L - \beta \cdot [\lambda \cdot \bar{J} + (1 - \lambda) \cdot J^c(\epsilon)]$$

The loan proves ineffective. The reason for this is that loans do not alter the fundamental surplus of firms and workers. This is because the constraint faced by the firm is not a simple liquidity constraint. To sustain employment, the joint surplus of firms and workers must increase. Short-time work achieves this by compensating workers for lost income when hours are reduced, thereby raising the joint surplus of the match.

3.5 Comparing Lay-Off Taxes and Short-Time Work

Having disentangled how the Ramsey planner uses lay-off taxes and short-time work to counteract the fiscal externalities created by unemployment insurance, it is now time to determine which is the superior policy tool. From a theoretical point of view, this cannot be definitively determined. While lay-off taxes do not introduce any inefficiencies into the economy and can, in fact, induce the efficient number of separations in unconstrained firms, they cannot counteract fiscal externalities on constrained firms. Short-time work, on the other hand, can act on constrained firms as well. This, though, comes at the price of distorted working hours. To determine which is more effective in practice, we focus on the quantitative analysis of the model in the remainder of the paper.

Corollary 2. *If there are no constrained firms in the economy (i.e., $p = 0$), the optimal lay-off tax increases welfare more than the optimal short-time work scheme.*

PROOF: This follows from the fact that lay-off taxes introduce no distortions but can fully eliminate inefficient separations in unconstrained firms. All inefficiencies that short-time work can act on but lay-off taxes cannot, drop out when $p = 0$.

It is also clear that short-time work is the superior policy instrument if all firms are constrained.

Corollary 3. *If there are no unconstrained firms in the economy (i.e., $p = 1$), the optimal short-time work scheme increases welfare more than the optimal lay-off tax.*

PROOF: This follows from the fact that the only inefficiency that lay-off taxes can act on, i.e., inefficient separations in unconstrained firms, cannot occur anymore. Short-time work can still act against inefficient separations in constrained firms and provide worker insurance.

In all cases with $p \in (0, 1)$, it is ambiguous which of the two policy regimes is superior without quantitative analysis, to which we turn next. It is clear, however, that as p increases, lay-off taxes gradually lose their advantage over short-time work. In the following sections, we turn to quantitatively assessing the relative performance of the two policy regimes for different values of p .

4 Calibration

We calibrate the model to the U.S. economy at monthly frequency, assuming CRRA utility: $u(c) = \frac{c^{1-\zeta}}{1-\zeta}$. Further, we set the coefficient of relative risk aversion ζ to the standard value of 2. Following Christoffel and Linzert (2010), we set the labor elasticity of the production function α to 0.65. The elasticity of matching with respect to unemployment γ is set to the standard value of 0.65. As customary, we set the worker bargaining power η to 0.65 to satisfy the Hosios condition (Hosios, 1990). Note that 0.65 falls within the range of estimates reported by Petrongolo and Pissarides (2001). The disutility of labor parameter ψ is set to 1.5 to target a Frisch elasticity of labor supply of 0.65, which is within the reasonable set of parameters according to Domeij and Floden (2006).

We set the shock arrival probability λ to 0.07, so that a firm will remain at any drawn productivity level for $1/0.07 = 14.29$ months on average. This choice is informed by the estimate of yearly plant-level autocorrelation of productivity of around 0.4 by Abraham

and White (2006).⁷

The location of the productivity shock distribution μ is set to -0.80 to normalize the average wage $\bar{w}$ to 1. Since the effective dispersion of productivity shocks is governed by the cost shock parameter c_f , which is calibrated internally, we set σ to 0.12 following Krause and Lubik (2007).

The remaining parameters are calibrated internally. The calibration targets are shown in Table 1. All targets are met exactly.

Table 1: Model calibration targets

Parameter	Description	Value
<i>Worker flows</i>		
q	Vacancy-filling rate	0.3381
f	Job-finding rate	0.41
ρ^{eff}	Effective monthly separation rate	0.03
<i>Policy parameters</i>		
b^{rep}	UI replacement rate	0.45
F^{rep}	Lay-off tax coverage of UI payments	0.5

Notes: $b^{\text{rep}} \equiv \frac{b}{w}$ denotes the unemployment insurance (UI) replacement rate, i.e. benefits b relative to the average wage w (normalized to 1 in the calibration). The lay-off tax coverage target is reported as $\frac{f}{b}F^{\text{cal}}$, i.e. what fraction of expected UI payments to a laid-off worker is covered by the lay-off tax F .

For the purpose of calibration, we set p to 0.5. We show that our results concerning relative effectiveness of short-time work and lay-off taxes are robust to even drastic changes of p during the calibration in Appendix C. We target a UI replacement rate $b^{\text{rep}} = \frac{b}{w}$ of 0.45 as reported by Engen and Gruber (2001). Following Jung and Kuester (2015), we target a lay-off tax coverage F^{rep} of 0.5, which means that the lay-off tax covers 50% of the expected UI payments transferred to a worker after a lay-off.⁸ Given these policy parameter targets to inform the calibration of b and F , we calibrate the remaining parameters (matching efficiency $\bar{m}$, cost shock scale c_f , and vacancy posting cost k_v) to match standard worker flow targets. Note that since ρ is the probability of separation conditional on a new shock arriving, the effective separation rate ρ^{eff} is different from ρ . It is given by $\rho^{\text{eff}} = \frac{n \cdot \lambda \cdot \rho + (1-n) \cdot f \cdot \rho}{n_0}$, where n_0 is the mass of matches at the beginning of a period. It includes the mass of already existing matches n and new matches $(1-n) \cdot f$. Existing matches draw a new shock with probability λ , while all new matches draw a

⁷In the model, the autocorrelation of productivity is given by $1 - \lambda$. Therefore, $\lambda = 0.07$ implies a monthly autocorrelation of 0.93, which implies a yearly autocorrelation of 0.42.

⁸Since the expected duration of unemployment is $1/f$, the expected UI payments per unemployed worker are given by $\frac{b}{f}$, implying that $F^{\text{rep}} = \frac{F \cdot f}{b}$.

productivity shock and, like every other match, will separate with probability ρ once productivity realizes.

Table 2 summarizes the calibrated and set parameters of the model.

Table 2: Model Parameters: Calibrated and Set Values

Parameter	Description	Value
Calibrated Parameters		
$\bar{m}$	Matching efficiency parameter	0.383
c_f	Cost shock parameter	0.407
k_v	Vacancy posting cost	0.086
b	Unemployment benefit level	0.450
$\bar{h}$	Regular working hours level	0.953
F^{cal}	Lay-off tax	0.549
Set Parameters		
ζ	Coefficient of relative risk aversion	2
α	Labor elasticity in production function	0.65
γ	Elasticity of matching w.r.t. unemployment	0.65
η	Worker bargaining power	0.65
ψ	Disutility of labor parameter	1.5
λ	Shock arrival probability	0.07
μ	Location of productivity shocks	-0.80
σ	Scale of productivity shocks	0.12
p	Fraction of financially constrained firms	0.5

5 Quantitative Results

5.1 Taking UI as given

As a first benchmark, we compute the optimal lay-off tax and short-time work parameters chosen by a Ramsey planner who takes the calibrated UI system (i.e. $b = 0.45$) as given. To calculate the Ramsey optimal policy parameters, we solve the Ramsey planner's maximization as described in Section 3.1 numerically. The details are described in Section M in the appendix.

Figure 1 shows the results for the optimal lay-off tax F across $p \in [0, 1]$. The result is what the FOC pinning down the optimal lay-off tax (Equation 2) lets us expect. The planner exactly offsets the fiscal externality on unconstrained firms $\frac{\lambda}{f} \cdot b$. Since this does not depend on p in any way, the level of the optimal lay-off tax F hardly changes across p . The slight downward slope is explained by general-equilibrium feedback effects in $BE_{\text{lt}}(b)$. At $p = 1$, lay-off taxes lose their bite completely as they can no longer target any inefficiencies. To illustrate this, we show the optimal lay-off tax to be $F = 0$. In fact,

any lay-off tax $F \in \mathbb{R}_+$ is optimal.

Figure 1: Optimal Lay-Off Tax

Notes: Optimal lay-off tax F chosen by the Ramsey planner for each value of $p \in [0, 1]$, normalized by the average wage $\bar{w}$. The unemployment benefit parameter is fixed at its calibrated value, $b = 0.45$

Figure 2 shows the Ramsey-optimal short-time work parameters across p . The way that the Ramsey planner sets the eligibility threshold reflects the trade-off described in Section 3.3 under Proposition 4: While there are only a few constrained firms in the economy, it is very costly to protect all firms, including constrained ones, from premature separations. Setting the eligibility constraint high enough to allow all constraint firms onto short-time work before they hit their separation threshold ξ_s^c will allow many unconstrained firms onto short-time work and collect windfall profits, even though they would not separate without it. As discussed, this introduces inefficient working hours distortions, and as long as only a few firms are constrained, these distortions outweigh the benefit of protecting these few constrained firms. The optimal eligibility threshold is therefore ξ_s^u . However, as the mass of constrained firms grows along the x-axis of Figure 8, the benefits from protecting constrained firms eventually outweigh the added distortion from protecting excess unconstrained firms. At this point ($p = 0.128$), the eligibility condition jumps to the threshold ξ_s^c at which constrained firms without short-time work separate.

The optimal generosity parameter s_{stw} is increasing in p except at the kink at $p = 0.128$. This is because, as discussed in the context of Proposition 5 in Section 3.3, the planner targets the *average* net subsidy. As constrained firms have less margin to adjust their hours, this means that s_{stw} has to rise in p as long as ϵ_{stw} does not change much. Additionally, the planner can provide more insurance with higher s_{stw} which becomes more valuable as p increases, also contributing to the upward slope. However, when ϵ_{stw} jumps to ξ_s^c , many more firms are suddenly on short-time work, introducing greater hours dis-

Figure 2: Optimal Short-time Work

Notes: Optimal eligibility threshold ϵ_{stw} and optimal short-time work benefits s_{stw} set by the Ramsey planner across $p \in [0, 1]$, normalized by the average wage $\bar{w}$. ξ^u is the separation threshold of an unconstrained firm without access to short-time work. ξ^c is the separation threshold of a constrained firm without access to short-time work. The calibrated UI parameter of $b = 0.45$ is taken as given.

tortion to the economy. To counteract that distortion, the planner reduces the s_{stw} as the more lenient eligibility threshold is introduced, explaining the kink.

Having established how the Ramsey planner sets both lay-off taxes and short-time work, it is now time to discuss which is the superior policy tool. Figure 8 shows the respective welfare induced by the optimal lay-off tax and the optimal short-time work schemes across p on the left. Unsurprisingly, welfare is decreasing in p in both cases as higher shares of firms become constrained. As expected, when there are no or only a few constrained firms, the lay-off tax is the superior policy tool. Crucially, however, the slopes are different for the two policy regimes: as p increases, lay-off taxes gradually lose effectiveness, leading to a faster decline of welfare. The two curves have different slopes and intersect at $p = 0.275$. The interpretation is simple: If more than 27.5% of firms are financially constrained, short-time work becomes the superior policy instrument; for smaller shares of constrained firms, lay-off taxes are the better tool.

For better interpretation, Figure 3 shows consumption equivalent variation (CEV). While welfare improvements in terms of consumption equivalent variation intersect at the exact same point as raw welfare functions, they carry two additional messages. Firstly, the resulting improvements of the respective superior policy scheme are substantial at every p , ranging around 0.95-1.25%. Secondly, as p increases, short-time work becomes not only preferable to lay-off taxes, but improvements in terms of consumption equivalent variation even increase. This stems from the effect that short-time work helps firms provide insurance, which becomes increasingly important for higher p .

Aggregate outcomes of the economies associated with both policy regimes are shown in Figure 11 in Appendix B.

Figure 3: Welfare Comparison

Notes: Plot (a) on the left shows welfare across $p \in [0, 1]$ of the economy with the optimal lay-off tax and the optimal short-time work regimes, respectively. The calibrated UI parameter of $b = 0.45$ is taken as given. Plot (b) on the right shows improvements of optimal short-time work and optimal lay-off taxes over the economy without either of these two policies, but with the calibrated UI parameter in terms of consumption equivalent variation.

5.2 Full Optimization

We now turn to the full optimization problem, where the Ramsey planner optimally chooses either lay-off tax or short-time work parameters simultaneously with the unemployment benefit. As a first benchmark, we compute how the Ramsey planner sets the optimal unemployment benefit b absent both lay-off taxes and short-time work. Figure 4 shows the result as a green dashed line. Without lay-off taxes that could counteract the fiscal externality of the unemployment benefit, the optimal unemployment benefit b is set to a lower level compared to the calibrated value of 0.45, ranging between 0.35 and 0.36. It slightly increases in p , indicating that the planner values higher insurance more than lowering unemployment when faced with more separations and therefore higher unemployment because of more constrained firms.

Having established how unemployment benefits are set in the absence of supplementary policies, we now turn to the problem of jointly optimizing the unemployment benefit b and the lay-off tax F . The first thing to note is that b is set considerably higher than without supplementary policies for $p < 1$ as shown by the blue line in Figure 4. This is because the planner now has the lay-off tax at her disposal to counteract the fiscal externality of the unemployment benefit, which allows her to set a higher unemployment benefit and thus provide more insurance to workers. The second thing to note is that

Figure 4: Optimal Unemployment Benefits

Notes: Panel (a) shows the optimal unemployment benefit b chosen by the Ramsey planner for each value of $p \in [0, 1]$, normalized by the average wage $\bar{w}$. The dashed green line corresponds to the case without layoff taxes or short-time work; the blue line allows the planner to set layoff taxes; and the orange line allows the planner to set short-time work. Panel (b) shows the corresponding unemployment rate u in each case.

b sharply decreases with p until it reaches the same level as without supplementary policies at $p = 1$. The reason behind this downward slope is that with more constrained firms, the lay-off tax that can only act on unconstrained matches becomes less and less effective at counteracting the fiscal externality of the unemployment benefit. This forces the planner to set a lower unemployment benefit to reduce the externality. Indeed, as the right panel of Figure 4 shows, the unemployment rates associated with the regime with no supplementary policies and the regime with the optimal lay-off tax converge as p increases until the two curves meet at $p = 1$ as well.

A secondary effect of this is that the optimal lay-off tax F shown in Figure 5 also decreases in p as the planner sets lower and lower unemployment benefits and thus has to counteract a smaller and smaller fiscal externality in unconstrained matches. At $p = 1$, the lay-off tax loses its bite completely, and the planner sets the same unemployment benefit as without the option to set a lay-off tax.

Next, we turn to the joint optimization of the unemployment benefit b and the short-time work parameters ϵ_{stw} and s_{stw} . Like with the lay-off tax, the optimal unemployment benefit b with short-time work shown in Figure 4 as an orange line is set at a higher level than without supplementary policies. Unlike with the lay-off tax, however, the optimal unemployment benefit b increases with p . The reason for this pattern is that with more constrained firms, more matches are at risk of separation, leading to higher welfare gains from providing insurance through the unemployment benefit. Since short-time work remains effective at counteracting the fiscal externality of the unemployment

Figure 5: Optimal Lay-Off Tax

Notes: The optimal lay-off tax F across $p \in [0, 1]$, normalized by the average wage $\bar{w}$, when the Ramsey planner optimally chooses the optimal lay-off tax F and the optimal unemployment benefit b simultaneously.

Figure 6: Optimal Short-time Work

Notes: Optimal STW eligibility threshold ϵ_{stw} and STW benefit s_{stw} chosen by the Ramsey planner for each value of $p \in [0, 1]$, while choosing the optimal unemployment benefit simultaneously. Benefits are normalized by the average wage $\bar{w}$. The thresholds ξ_s^u and ξ_s^c denote the separation thresholds of unconstrained and constrained firms without access to Short-time work, respectively.

benefit even with more constrained firms, the planner is not kept from increasing b by increasing the number of separations as with the lay-off tax. As the right panel of Figure 4 shows, the unemployment rate under the short-time work regime remains much lower for higher p than in the other regimes as a result.

This dynamic also explains how the optimal short-time work parameters ϵ_{stw} and s_{stw} shown in Figure 6 are set differently than in the case without optimizing b discussed in the previous section. The qualitative patterns of the optimal eligibility thresholds persist: the planner still initially sets $\epsilon_{\text{stw}} = \xi_s^u$ before transitioning to $\epsilon_{\text{stw}} = \xi_s^c$ as p increases for the same reasons described in Section 5.1. However, there are quantitative differences. Both ξ_s^u and with it the eligibility threshold, now increase with p , reflecting that higher unemployment benefits lead to higher separation thresholds and thus firms are in need of support sooner. Meanwhile, the optimal short-time work generosity parameter s_{stw} increases far more steeply in p than in the case where b is held fixed. This sharp increase arises because the higher unemployment benefits amplify the fiscal externality that the planner must counteract, necessitating a much higher short-time work generosity to keep the average net subsidy at the optimal level.

Figure 7: Welfare Comparison

Notes: Plot (a) on the left shows welfare across $p \in [0, 1]$ of the economy with the optimal lay-off tax and the optimal short-time work regimes, respectively, while the Ramsey planner optimally chooses the optimal unemployment benefit b simultaneously. Plot (b) on the right shows improvements of optimal short-time work and optimal lay-off taxes over the economy without either of short-time work or lay-off taxes, as well as without setting b optimally, but with the calibrated UI parameter in terms of consumption equivalent variation.

Finally, we compare the welfare of the optimal lay-off tax and the optimal short-time work when the Ramsey planner optimally sets the unemployment benefit b simultaneously. Figure 7 shows the results. As expected, the welfare of both optimal policies is higher than without optimizing b . The improvement over an economy with calibrated UI parameters but without either lay-off taxes or short-time work in terms of consumption-equivalent

variation is substantial especially for higher values of p . The improvement over the benchmark economy with only the calibrated unemployment insurance and neither short-time work nor lay-off taxes is around 1.2% with short-time work instead of around 1% and close to 1.35% with lay-off taxes instead of around 1.25% for $p = 0$. In particular, in the case of full optimization, short-time work becomes the superior policy instrument at an even lower share of financially constrained firms of $p = 0.236$ compared to $p = 0.275$ when b is held fixed.

5.3 Optimal Joint Design of STW and Lay-off Taxes

As discussed in the previous sections, both short-time work and lay-off taxes have advantages and disadvantages. Lay-off taxes do not introduce distortions, but unlike short-time work, they cannot act on financially constrained firms. Therefore, it is only natural to ask whether both systems can be combined to take full advantage of the strengths of both schemes. Indeed, many states in the U.S. implement both systems simultaneously, lending this question practical relevance.⁹ In this section, we characterize the Ramsey-optimal combination of short-time work and lay-off taxes and quantitatively assess how much it improves upon using only one of the two systems.

The rationale for combining both policy tools is straightforward: Ideally the planner would like to use lay-off taxes to deter inefficient separations in unconstrained firms without introducing any new distortions, and a short-time work program only to target the same inefficiency in constrained firms. However, because the government cannot perfectly distinguish between firm types, any eligibility condition that grants constrained firms access to short-time work will inevitably allow unconstrained firms to participate as well. In these unconstrained firms, layoff taxes already prevent inefficient separations, making short-time work redundant. This creates pure windfall effects that generate costly distortions in working hours without achieving additional efficiency gains.

The Ramsey planner must therefore weigh the benefits from supporting constrained matches against the costs of windfall effects when introducing short-time work on top of lay-off taxes. This tradeoff is reflected by how the Ramsey planner sets the policy parameters. Proposition 6 formalizes how the planner sets the optimal lay-off tax and the optimal short-time work benefits when optimizing over both systems simultaneously:

⁹Lay-off taxes are implemented through experience-rated unemployment insurance systems. Short-time work exists under the name short-time compensation in more than half of the states, though it is rarely used according to Krolikowski and Weixel (2020).

Proposition 6. *The optimal lay-off tax and STW can be expressed as:*

$$\begin{aligned}\bar{s}_{stw} &= \frac{T_{UI}}{T_{stw}} \cdot b - \omega^u \cdot \lambda \cdot F + \frac{MIE_{stw}^c}{MMS_{stw}} - \frac{MWL_{stw}}{MMS_{stw}} + BE_{stw} \\ F &= T_{UI} \cdot b - (1 - \omega^\xi) \cdot T_{stw} \cdot s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u)) + BE_F\end{aligned}$$

Here ω^u denotes the fraction of marginal firms that are unconstrained and saved with STW. ω^ξ denotes the fraction of marginal firms that separated and did not have access to STW in unconstrained firms.

PROOF: See section N in the appendix.

Proposition 6 yields the same optimal formulas for STW benefits and layoff taxes as in the single-instrument cases in Propositions 2 and 5, except for one key modification: the optimal STW benefits are reduced by the term $\omega_u \cdot \lambda \cdot F$, which depends on the optimal layoff tax, while the optimal layoff tax is reduced by the term $(1 - \omega_\xi) \cdot T_{stw} \cdot s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_{sc}))$, which depends on the optimal STW benefits. Consequently, when the planner implements both policies simultaneously, both the layoff tax F and the short-time work generosity s_{stw} are set at lower levels than when either policy is implemented in isolation.

The underlying mechanism is straightforward: Since unconstrained firms have access to short-time work despite not requiring support, both policy instruments work to prevent separations. This dual approach risks over-detering separations and thereby hindering efficient reallocation of workers from less productive to more productive firms. To prevent costly misallocation, the planner scales back both instruments. This tradeoff is reflected in the optimal policy: higher STW generosity requires lower layoff taxes, and vice versa. As in the model with only short-time work, the Ramsey planner also chooses the eligibility condition for short-time work. To provide additional insight into the interaction between short-time work, lay-off taxes, and the share of constrained firms in the economy, Corollary 4 considers two special cases. The first is a loose eligibility condition under which all constrained firms that would otherwise separate can access short-time work. The second is a strict eligibility condition that excludes all constrained firms from short-time work.

Corollary 4. *(i) Suppose the planner has already set a loose eligibility condition that allows all firms that would otherwise separate to enter short-time work. Then $\omega^\xi = 0$ and $\bar{s}_{stw}$ is pinned down by the simplified condition*

$$s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^c)) = \frac{\lambda}{f} \cdot b + \frac{1}{1 - \omega^u(p)} \cdot \left[\frac{MIE_{stw}^c}{MMS_{stw}} - \frac{MWL_{stw}}{MMS_{stw}} \right] + BE_{stw}. \quad (8)$$

In this case, if $p \rightarrow 0$, then $s_{stw} = 0$.

(ii) Suppose the planner has already set the eligibility condition so strictly that constrained firms cannot access short-time work. Then $\omega^u = 1$ and $s_{stw} = 0$.

PROOF: See Section N.1 in the appendix

Corollary 4 reveals that, in the case of the loose eligibility condition, almost the same formula as in Proposition 5 pins down s_{stw} . The main difference is the multiplier term $M = 1/(1 - \omega^u(p))$. This sheds light on how p affects the generosity of short-time work: as p falls, fewer workers require income insurance via STW benefits, reducing the marginal insurance effect $MIE_{s_{stw}}^c$. Simultaneously, windfall effects intensify as more unconstrained firms access STW despite not requiring support. This is captured by the multiplier term M , which inflates the costs of working-hours distortion $\frac{MW L_{s_{stw}}}{MMS_{s_{stw}}}$ per worker. The multiplier increases with the fraction of unconstrained firms saved by STW, $\omega^u(p)$. In the limiting case where p approaches 0, all firms accessing STW would be unconstrained, leading the planner to set STW benefits to zero.

If, on the other hand, the eligibility condition is set strictly enough to screen out all constrained firms from short-time work support, the short-time work scheme is obsolete, as all inefficiencies in constrained firms are better tackled using the lay-off tax, and the planner sets s_{stw} to 0.

Given these results, both a combination of short-time work and lay-off taxes and using only lay-off taxes could be optimal in practice. We therefore turn to numerical evaluations of the optimal policy mix to determine how the planner sets both policy tools simultaneously in the calibrated model.

Figure 8: Optimal Joint Design of Lay-off Taxes and STW Benefits

Notes: Optimal lay-off tax F and optimal short-time work benefits s_{stw} set by the Ramsey planner across $p \in [0, 1]$. Both are normalized by the average wage $\bar{w}$. The calibrated UI parameter of $b = 0.45$ is taken as given.

Figure 8 shows how the Ramsey planner optimally sets the lay-off tax F and the short-

time work generosity s_{stw} in the calibrated model. Appendix E discusses the corresponding eligibility condition. There are two key takeaways from Figure 8. First, for small p , there are no measurable welfare gains from combining lay-off taxes with STW. The planner chooses to ignore short-time work and implements the optimal lay-off tax regime. Only once at least 6.3% of firm matches are financially constrained does the benefit of introducing short-time work outweigh the social cost of windfall effects among unconstrained firms. Second, the more important protecting constrained matches becomes as p increases, the more the planner relies on short-time work instead of lay-off taxes to impede inefficient separations. This is evident from the downward slope of F and the upward slope of s_{stw} in p .

Figure 9: Joint Optimal Design Welfare

Notes: The plot shows improvements from optimal short-time work, optimal lay-off taxes, and the optimal joint design over the economy without either short-time work or lay-off taxes, and without setting b optimally, but with the calibrated UI parameter in terms of consumption equivalent variation.

Figure 9 compares welfare induced by the independently optimal policy regimes with that induced by the joint optimization in terms of CEV. While the joint implementation always weakly dominates using only one of the two policy instruments, gains from implementing the joint policy are the greatest around $p = 0.3$. For p close to 1 or 0, the combination of short-time work and lay-off taxes hardly improves upon using the optimal individual policy tools. This highlights that in economies with only few constrained firms, lay-off taxes work well, and in economies with many constrained firms, short-time work is very effective. In economies with a large number of both constrained and unconstrained firms, however, implementing the optimal combination leads to more sizable improvements.

6 Discussion: How large is p ?

The fact that the relative effectiveness of short-time work and lay-off taxes depends on the value of p raises the question of how large p is in practice. However, there are some challenges connected with mapping p to moments that are observable from empirical data.

First, the empirical literature uses a variety of definitions, proxies, and data sources to identify financially constrained firms, and there is no single universally accepted measure. Second, existing methods often rely on observable binding financial constraints, e.g. by observing rejected loan applications. In the model p is the share of worker-firm matches that cannot *ex post* borrow beyond its expected value, i.e. the share of matches without access to full Arrow-Debreu state contingent contracts. Therefore, measuring p amounts to measuring the share of workers in the economy who can not be retained by their employers because of insufficient credit in some *potential* states that may never materialize. Taking our model calibration as given, it is possible, however, to back out the value of p implied by and estimate for the share of firms with binding financial constraints. This relationship is shown in Figure 14. In what follows, we relate p to existing empirical measures of financial constraints among firms, which provides guidance on its plausible magnitude.

Figure 10: Empirical Value of p

Notes: The figure maps the model parameter p to the model-implied share of firms with binding borrowing constraints. The solid blue line gives this mapping. The shaded areas indicate where lay-off taxes (LT) and short-time work (STW) are welfare-superior, respectively. The dotted horizontal lines correspond to empirical estimates of financially constrained firms from Hadlock and Pierce (2010) and the U.S. Bureau of Labor Statistics (2025), while the solid vertical lines show liquidity-based benchmarks from Pursell and Hussey (2025) and Farrell and Wheat (2016).

Hadlock and Pierce (2010) classify Compustat firms into categories of being affected

by financial constraints. Under their preferred specification, 6.9% of firms are either financially constrained (FC) or likely financially constrained (LFC). FC firms show clear evidence of binding financing problems, while LFC firms report difficulties obtaining financing but without evidence that these constraints have yet affected investment. If, on the other hand, we interpret firms from FC and LFC firms as being the firms with binding financial constraints, this implies $p = 0.33$. If on the other hand we interpret LFC as containing all firms with potentially binding constraints this would rationalize $p = 0.069$. The Hadlock and Pierce (2010) estimate therefore implies plausible estimates in the interval $[0.069, 0.33]$ ¹⁰.

It is worth noting that Hadlock and Pierce (2010) draw on Compustat data, which cover only publicly traded firms and thus skew toward larger firms. Hadlock and Pierce (2010) themselves show that smaller firms are more likely to be financially constrained. Indeed, since p is the share of constrained one-on-one matches, a natural interpretation is that these matches exist within larger firms. Under this interpretation, it seems likely that funds sufficient to retain workers can be shifted around within large firms relatively easily and that most constrained matches exist within small firms, making short-time work particularly suitable for protecting matches in small firms. Drawing on the Small Business Credit Survey (2026) and using data from the U.S. Bureau of Labor Statistics (2025), we calculate that 37% of small-business workers are employed at financially constrained firms that have either had loan applications at least partially rejected or did not apply for loans despite needing them (see Appendix D for details). A natural interpretation is that p must at least amount to 37% among small firms. To produce a share of firms at binding borrowing constraints of even around 30%, in the model p would have to be 1, emphasizing that the Compustat based estimates likely fall short of the real figure.

As a simple back-of-the-envelope calculation, one can combine the two benchmarks using employment shares. Publicly traded Compustat firms account for about 23% of employment (Schlingemann and Stulz, 2022), while we calculate firms small enough to be covered by the Small Business Credit Survey (2026) to account for roughly 50% of employment based on U.S. Bureau of Labor Statistics (2025) data. Using conservative values for both groups, namely 0.069 for Compustat firms and 0.37 for small firms, gives an employment-weighted benchmark of about 27.51% among the covered workers.¹¹

Finally, we consider two liquidity-based measures. Pursell and Hussey (2025) report that roughly 41% of firms hold less than one month of liquid reserves, while Farrell and Wheat (2016) find that 50% of firms hold fewer than 27 days of cash buffer. These firms may

¹⁰The value 0.33 likely is an overly high estimate for p in this sample, as binding credit constraints need not map one-to-one onto binding payroll constraints; 0.069 likely is a very low estimate, as firms already facing binding credit constraints can be expected to also face binding payroll constraints when hit by a negative productivity shock.

¹¹This calculation is only illustrative: the two empirical measures are not directly comparable and the remaining workers who neither work in publicly traded nor small firms are excluded.

be unable to absorb sufficiently adverse productivity shocks, making the two estimates natural direct benchmarks for p .

Taken together, we interpret these findings as suggesting that values of $p > 0.275$ are empirically plausible, in which case short-time work may be the superior policy instrument. All of the estimates point to a value of $p > 0.063$ implying that the optimal combination of short-time work and lay-off taxes leads to welfare improvements over implementing only a lay-off tax. We stress, however, that further empirical validation is needed to more directly discipline the value of p .

7 Conclusion

We set out by asking the simple question, which of the two policy tools that policy makers in many countries already employ - lay-off taxes or short-time work - is better at counteracting the fiscal externalities of unemployment insurance. While existing literature emphasizes desirable properties of lay-off taxes, we show that their effectiveness is highly sensitive to the assumption that firms are unconstrained in their ability to smooth shocks.

By introducing firm-level financial constraints into a rich yet tractable Diamond-Mortensen-Pissaridis search-and-matching framework (DMP) with endogenous separations, risk-averse workers, and flexible working hours, we show that lay-off taxes struggle with counteracting these externalities when firms are constrained. Short-time work schemes, on the other hand, can act on constrained firms but have the disadvantage of introducing new inefficiencies into the economy through distorting working hours.

Our theoretical analysis, grounded in a Ramsey policy approach, delivers closed-form expressions for optimal lay-off taxes and short-time work subsidies as a function of the share of financially constrained firms. We show that lay-off taxes are the superior policy instrument with no or only a few financially constrained firms, but that short-time work benefits are better if sufficient firms are financially constrained. Quantitatively, we find that when 27.5% or more of firms are financially constrained, short-time work dominates lay-off taxes in welfare terms. If the level of unemployment benefits is optimized simultaneously, this threshold falls to 23.6%. We proceed to show that combining both short-time work and lay-off taxes can be superior to using only one of the two policy schemes. We find that this leads to non-negligible welfare gains in economies with a medium share of constrained firms.

Policy recommendations must therefore depend on the prevalence of financial constraints in an economy. Anecdotally, it seems highly plausible that in the U.S., where a lay-off tax is implemented through experience-rated unemployment insurance, financial constraints play a smaller role than in countries like Germany or France with less developed financial

sectors and smaller firms where short-time work is widely used. When relating existing empirical evidence of how prevalent financial constraints are in the U.S., it emerges, however, that it is empirically plausible that even in the U.S. short-time work may be the superior policy tool in particular for small businesses. Still, empirically determining the exact extent of financial constraints in the U.S. and in other countries and the implications for optimal policy remain key.

Another interesting way forward is to explore how our results change over the business cycle. It is well documented, that financial constraints tighten during downturns. Because of this, there could be a case for relying more on short-time work during downturns and more on lay-off taxes during good times.

We believe this offers a promising direction for future research.

A Table of Model Parameters, Variables and Functions

Table 3: Important Variables and Functions

Parameter	Description
<i>Notation</i>	
(u / c)	Financially unconstrained/ constrained
p	Fraction financially constrained firms
<i>Policy</i>	
D	Minimum hours reduction threshold (Eligibility condition)
s_{stw}	STW benefits
b	UI benefits
τ	Tax on firms
F	Lay-off tax
<i>Productivity Thresholds</i>	
ϵ_{stw}	Eligibility threshold
$\epsilon_s^u, \epsilon_s^c$	Separation thresholds (u/ c, under STW)
ξ_s^u, ξ_s^c	Separation thresholds (u/ c, no STW)
ϵ^p	Productivity where financial constraint binds
<i>Production</i>	
ϵ	Idiosyncratic productivity
$g(\epsilon), G(\epsilon)$	Pfd and cdf of idiosyncratic productivity shock
$h(\epsilon), h_{stw}(\epsilon)$	Working hours on and off STW
$y(\epsilon, h)$	Production function
$\phi(h)$	Disutility of work
$z(\epsilon, h), z$	Realized and expected output net of disutility
$z(\epsilon), z_{stw}(\epsilon)$	Shorthand for $z(\epsilon, h)$ on and outside STW
<i>Firms and Firm Owner</i>	
$J^u(\epsilon), J^c(\epsilon)$	Realized firm value (u/ c, no STW)
$J_{stw}^u(\epsilon), J_{stw}^c(\epsilon)$	Realized Firm value (u/ c, under STW)
$\bar{J}$	Expected firm value
Π	Dividends
$w^u(\epsilon), w^c(\epsilon)$	(Monthly) Wage functions (u/ c, no STW)
$w_{stw}^u(\epsilon), w_{stw}^c(\epsilon)$	(Monthly) Wage function (u/ c) under STW
ν^f	Number of firm owners
c^f	Consumption firm owners

Table 4: Important Variables and Functions

Parameter	Description
<i>Worker</i>	
$V^u(\epsilon), V^c(\epsilon)$	Worker value (u/ c, no STW)
$V_{stw}^u(\epsilon), V_{stw}^c(\epsilon)$	Worker value (u/ u, with STW)
$\bar{V}$	Expected worker value
U	Value of unemployment
c^w	Constant consumption-equivalent
$c^w(\epsilon)$	Constrained consumption-equivalent function
$c_{stw}^w(\epsilon)$	Constrained consumption-equivalent function STW
<i>Labor Market</i>	
n	Mass of employed workers
n^s	Mass of matches receiving new shock
n^u, n^c	Mass of workers at u/c firms
$u = 1 - n$	Mass of unemployed workers
v	Mass of posted vacancies
$\theta = \frac{v}{1-n}$	Labor market tightness
f	Job-finding rate
q	Vacancy-filling rate
ρ	Separation rate
ρ^u, ρ^c	Separation rates (u / c)
<i>From Propositions</i>	
$\Omega(\epsilon)$	Welfare Costs STW in match at productivity ϵ
Ω^u	Average welfare loss STW in (u/ c) firms
Ω	Average welfare loss net of disutility of all firms
T_{UI}	Expected time a separated worker spends on UI
T_{STW}	Expected time a worker spends on STW
BE_i	Bargaining Effect
L_v	Social value of a new hire
L_s^u, L_s^c	Social value of the marginal worker in (u / c) firms
$L_{s,\xi}^c$	Social value of the marginal worker in c firm without STW
MMS_{stw}	Marginal number of matches preserved with STW benefits
MMS_{stw}^u, MMS_{stw}^c	Marginal number of matches preserved with STW benefits in (u/ c) firms
MWL_{stw}	Marginal welfare loss caused by STW benefits
MWL_{stw}^u, MWL_{stw}^c	Marginal welfare loss in (u/ c) firms caused by STW benefits
$MMS_{\epsilon_{stw}}$	Marginal number of matches added to STW with looser eligibility threshold
$MMS_{\epsilon_{stw}}^u, MMS_{\epsilon_{stw}}^c$	Marginal number of matches added to STW with a looser eligibility threshold in (u/ c) firms
$MWL_{\epsilon_{stw}}$	Marginal welfare loss caused by looser eligibility threshold.
$MWL_{\epsilon_{stw}}^u, MWL_{\epsilon_{stw}}^c$	Marginal welfare loss in (u/ c) firms caused by looser eligibility threshold.
MIE_b^c	Marginal insurance loss in c firms caused by UI benefits
$MIE_{stw}^c, MIE_{\epsilon_{stw}}^c$	Marginal insurance gain in c firms caused by higher STW benefits, looser eligibility threshold

B Aggregate Outcomes

Figure 11: Aggregate Outcomes

Notes: Aggregate outcomes for the different policy regimes taking the calibrated unemployment benefit level of $b = 0.45$ as given against the share of constrained firms, p . The red lines are associated with a regime with no lay-off tax and no short-time work, the blue lines with a regime with optimal UI benefits, and the orange lines with optimal short-time work. **(a)** Unemployment rate, **(b)** separation rate, **(c)** job finding rate and **(d)** output.

Figure 12: Aggregate Outcomes - Full Optimization

Notes: Aggregate outcomes for the different policy regimes (calibrated UI, optimal UI, optimal UI with optimal LT and optimal UI with optimal STW) as a function of the share of constrained firms, p . (a) Unemployment rate, (b) separation rate, (c) job finding rate and (d) output.

C Calibration Robustness

In our calibration, we set $p = 0.5$. We do this because, as discussed in Section 6, there is no universally accepted estimate for p . However, as Figure 13 shows, our main result, namely for which values of p short-time work is superior to lay-off taxes, hardly changes when using $p = 0.1$ or $p = 0.9$ during the calibration instead, showing that our results do not depend on our choice of p during the calibration.

Figure 13: Impact of Chaning p

Notes: Solid lines show welfare under short-time work; dashed lines show welfare under the lay-off tax. Each color corresponds to a different calibration value of (p). Dots mark the (p) at which the two welfare curves intersect for that calibration. Labels report the difference between each intersection and the middle-calibration intersection; the middle point is left unlabeled.

D Empirical Value of p

Figure 14: Empirical Value of p

Notes: The figure determines the fraction of firms that are financially constrained. The x-axis describes the number of firms p that have a financial constraint. The blue line shows the fraction of firms in the economy whose financial constraint is binding. The dashed line marks the 45-degree line. The green line marks the p -value after which STW is superior to lay-off taxes. The vertical lines labeled SBCS 1 - 4 show different degrees of financial constraints.

The figure illustrates how the measure of financial constraints drawn from Small Business Credit Survey (2026) is constructed. SBCS 1 captures the fraction of firms whose loan applications were denied outright. SBCS 2 adds firms that did not apply for financing despite needing it, for instance, because they expected rejection or were averse to taking on debt. Small Business Credit Survey (2026) refers to these firms collectively as having unmet financing needs. SBCS 3 further adds firms that had between 1 and 49 percent of their requested financing approved, and SBCS 4 adds firms that had between 50 and 99 percent approved. Small Business Credit Survey (2026) refers to firms in SBCS 1, SBCS 3, and SBCS 4, those that received no or only partial loan approval, as firms with financing shortfalls.

E Optimal Eligibility Condition Joint Optimal Design

Numerically, we can show that in our calibration, that the Ramsey planner can fully screen out financially constrained firms. The reason for this is that unconstrained firms

are deterred from separation via the lay-off tax while financially constrained firms are not. When it comes to the eligibility condition, the most important decision the Ramsey planner can take is whether to screen out workers or not. If he decides to screen out constrained workers, corollary 4 argues that the planner sets the STW benefits to zero, eliminating the STW system.

The planner decides to implement the STW system when the social value of the preserved matches outweighs the social costs of working hours distortion imposed on unconstrained firms, respectively the social costs of additional windfall effects. For $\epsilon_{stw} \in [\epsilon_s^c, \xi_s^c]$ we get:

$$\underbrace{MMS_{\epsilon_{stw}}^c \cdot L_{s,\epsilon}^c(\epsilon_{stw})}_{\text{Social value of preserved matches}} > \underbrace{MWL_{\epsilon_{stw}}^u}_{\text{Social cost of hours distortion in unconstrained firms}} + BE_{stw,2} \quad \forall \epsilon \in I,$$

From the formula we see again that the decision depends on the number of financially constrained firms, respectively, the number of constrained matches that can be saved with STW, $MMS_{\epsilon_{stw}}^c$. If this number is small, the costs of hours distortion might outweigh the welfare gain from rescuing additional workers.

Figure 15: Optimal Eligibility Condition, Joint Optimal Design

Notes: Optimal eligibility threshold ϵ_{stw} set by the Ramsey planner across $p \in [0, 1]$. ξ_s^u is the separation threshold of an unconstrained firm without access to short-time work. ξ_s^c is the separation threshold of a constrained firm without access to short-time work. The calibrated UI parameter of $b = 0.45$ is taken as given.

Figure 15 illustrates the results numerically for the optimal eligibility condition under the joint optimal design. For $p < 6.3\%$, the figure shows a red region, corresponding to the Ramsey planner's decision to forgo STW entirely. Beyond this threshold, the optimal eligibility condition is set equal to the separation threshold of constrained firms, which remains relatively stable as the fraction of constrained firms increases. Note that the

separation threshold of unconstrained firms without access to STW rises as the lay-off tax falls.

F Equilibrium Lay-Off Tax

F.1 Bargaining

Nash-Bargaining Problem:

$$\max_{w^u(\epsilon), w^c(\epsilon), h^u(\epsilon), h^c(\epsilon), \epsilon_s^u, \epsilon_s^c} \bar{J}^{(1-\eta)} (\bar{V} - U)^\eta$$

subject to

1. Financial constraint of financially constrained firms:

$$y(\epsilon, h(\epsilon)) - w^c(\epsilon) + \beta \cdot [\lambda \cdot \bar{J} + (1 - \lambda) \cdot J^c(\epsilon)] \geq 0$$

2. Commitment problem (Worker):

$$V^c(\epsilon) \geq U, \quad V^u(\epsilon) \geq 0$$

First of all, note that we can rewrite the financial constraint as

$$z(\epsilon) - c^c(\epsilon) + \beta \cdot [\lambda \cdot \bar{J} + (1 - \lambda) \cdot J^c(\epsilon)] \geq 0$$

Second, we can integrate the commitment problem of the worker into the value functions for the firm and worker surplus. For $i \in \{c, u\}$, we can rearrange the condition as:

$$u(c^i(\epsilon)) - u(b) + (\lambda - f) \cdot \beta \cdot (\bar{V} - U) \geq 0$$

Let $\epsilon_s^{i, \text{cp}}$ denote the threshold at which the worker wants to separate unitarily:

$$u(c^i(\epsilon_s^{i, \text{cp}})) - u(b) + (\lambda - f) \cdot \beta \cdot (\bar{V} - U) = 0$$

We can rewrite the value functions of the firm and the surplus of the worker as:

$$\begin{aligned}
\bar{J} &= -\tau \\
&+ (1-p) \cdot \int_{\max\{\epsilon_s^{u,B}, \epsilon_s^{u,CP}\}}^{\infty} \frac{z(\epsilon) - c^u(\epsilon) + \lambda \cdot \beta \cdot \bar{J}}{1 - \beta \cdot (1 - \lambda)} dG(\epsilon) \\
&+ (1-p) \cdot G(\max\{\epsilon_s^{u,B}, \epsilon_s^{u,CP}\}) \cdot \beta \cdot F \\
&+ p \cdot \int_{\max\{\epsilon_s^{c,B}, \epsilon_s^{c,CP}\}}^{\infty} \frac{z(\epsilon) - c^c(\epsilon) + \lambda \cdot \beta \cdot \bar{J}}{1 - \beta \cdot (1 - \lambda)} dG(\epsilon) \\
&+ p \cdot G(\max\{\epsilon_s^{c,B}, \epsilon_s^{c,CP}\}) \cdot \beta \cdot F \\
(\bar{V} - U) &= (1-p) \cdot \int_{\max\{\epsilon_s^{u,B}, \epsilon_s^{u,CP}\}}^{\infty} \frac{u(c^u(\epsilon)) - u(b) + \lambda \cdot \beta \cdot (\bar{V} - U)}{1 - \beta \cdot (1 - \lambda)} dG(\epsilon) \\
&+ p \cdot \int_{\max\{\epsilon_s^{c,B}, \epsilon_s^{c,CP}\}}^{\infty} \frac{u(c^c(\epsilon)) - u(b) + \lambda \cdot \beta \cdot (\bar{V} - U)}{1 - \beta \cdot (1 - \lambda)} dG(\epsilon)
\end{aligned}$$

Note that $\epsilon_s^{i,B}$ denotes the separation threshold in the bargaining outcome. Separations occurs either when the productivity falls below the bargained separation threshold or when the commitment constrained of the worker is violated $\epsilon < \max\{\epsilon_s^{c,B}, \epsilon_s^{c,CP}\}$. Finally, note that it is equivalent to maximize over $w^i(\epsilon)$ and $c^i(\epsilon)$ as

$$c^i(z) = w^i(\epsilon) - \phi(h^i(\epsilon)).$$

Set up Kuhn-Tucker Problem:

$$\max_{c^c(\epsilon), c^u(\epsilon), h^c(\epsilon), h^u(\epsilon), \epsilon_s^{c,B}, \epsilon_s^{u,B}} \mathcal{B}$$

where

$$\begin{aligned}
\mathcal{B} &= (\bar{J})^\eta \cdot (\bar{V} - U)^{1-\eta} \\
&- \int_0^\infty \mathcal{M}(\epsilon) [z(\epsilon) - c^c(\epsilon) + \beta \cdot [\lambda \cdot \bar{J} + (\lambda - f) \cdot J^c(\epsilon)]] d\epsilon
\end{aligned}$$

With Kuhn-Tucker conditions for a maximum:

$$\begin{aligned}
(I) \quad &\mathcal{M}(\epsilon) \leq 0 \\
(II) \quad &\mathcal{M}(\epsilon) \cdot [z(\epsilon) - c^c(\epsilon) + \beta \cdot [\lambda \cdot \bar{J} + (1 - \lambda) \cdot J^c(\epsilon)]] = 0
\end{aligned}$$

FOC for consumption equivalent of unconstrained firms:

$$\begin{aligned}
\frac{\partial \mathcal{B}}{\partial c^u(\epsilon)} &= -(1-\eta) \cdot (1-p) \cdot g(\epsilon) \cdot \left(\frac{\bar{V} - U}{\bar{J}} \right)^\eta \\
&\quad + \eta \cdot (1-p) \cdot g(\epsilon) \cdot u'(c^u(\epsilon)) \cdot \left(\frac{\bar{J}}{\bar{V} - U} \right)^{1-\eta} \\
&= 0 \\
\iff \frac{1-\eta}{\eta} \cdot \frac{\bar{V} - U}{\bar{J}} &= u'(c^u(\epsilon)) \quad \Rightarrow \quad u'(c^u(\epsilon)) = u'(c^w)
\end{aligned}$$

Note that the firm wants to perfectly insure workers against idiosyncratic productivity shocks as long as they are unconstrained.

Define the joint surplus as

$$\bar{S} = \bar{J} + \frac{\bar{V} - U}{u'(c^w)}$$

The resulting surplus splitting rule gives:

$$J = (1-\eta) \cdot \bar{S}, \quad \frac{\bar{V} - U}{u'(c^u)} = \eta \cdot \bar{S}$$

FOC for consumption equivalent of constrained firms:

$$\begin{aligned}
\frac{\partial \mathcal{B}}{\partial c^c(\epsilon)} &= -(1-p) \cdot g(\epsilon) \cdot (1-\eta) \cdot \left(\frac{\bar{V} - U}{\bar{S}} \right)^\eta \\
&\quad + (1-p) \cdot g(\epsilon) \cdot u'(c^u(\epsilon)) \cdot U \cdot \left(\frac{J}{\bar{V} - U} \right)^{1-\eta} \\
&\quad + \mathcal{M}(\epsilon) \stackrel{!}{=} 0
\end{aligned}$$

Insert the surplus splitting rule:

$$\begin{aligned}
\Rightarrow & \quad -(1-p) \cdot g(\epsilon) \cdot \left(\frac{\eta}{1-\eta} \cdot u'(c^w) \right)^\eta \\
&\quad + (1-p) \cdot g(\epsilon) \cdot u'(c^c(\epsilon)) \cdot \eta \\
&\quad + \mathcal{M}(\epsilon) \cdot \left(u'(c^w) \cdot \frac{1-\eta}{\eta} \right)^{1-\eta} = 0 \\
\iff & \quad (1-p) \cdot g(\epsilon) \cdot \eta \cdot (u'(c^c(\epsilon)) - u'(c^w)) = -\mathcal{M}(\epsilon) \cdot \left(u'(c^u) \cdot \frac{\eta}{1-\eta} \right)^{1-\eta}
\end{aligned}$$

Note that if $c^c(\epsilon) < c^w$, then the RHS of the equation is positive due to risk aversion. Thus, firms and workers gain joint surplus until $c^c(\epsilon) = c^w$.

If

$$z(\epsilon) - c^w + \beta \cdot [\lambda \cdot \bar{J} + (1 - \lambda) \cdot J^c(\epsilon)] \geq 0$$

then the constraint is non-binding and $\mathcal{M}(\epsilon) = 0$. ✓

If

$$z(\epsilon) - c^w + \beta \cdot [\lambda \cdot \bar{J} + (1 - \lambda) \cdot J^c(\epsilon)] < 0$$

then the constraint is binding and $\mathcal{M}(\epsilon) < 0$. ✓

Thus, it is optimal for the firm to pay as much as it can:

$$J^c(\epsilon) = z(\epsilon) - c^c(\epsilon) + \beta \cdot [\lambda \cdot \bar{J} + (1 - \lambda) \cdot J^c(\epsilon)] = 0$$

$$\Leftrightarrow c^c(\epsilon) = z(\epsilon) + \lambda \cdot \beta \cdot \bar{J}$$

Using the surplus splitting rule, the Nash-Bargaining problem can be simplified to

$$\max_{w^u(\epsilon), w^c(\epsilon), h^u(\epsilon), h^c(\epsilon), \epsilon_s^u, \epsilon_s^c} (1 - \eta)^{(1-\eta)} \cdot (u'(c^w)\eta)^\eta \cdot \bar{S}$$

That is, we just have to maximize the joint surplus with the remaining contracts:

$$\begin{aligned} \bar{S} &= -\tau \\ &+ (1 - p) \cdot \int_{\max\{\epsilon_s^{u,B}, \epsilon_s^{u,CP}\}}^{\infty} \frac{z(\epsilon) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + (1 - \eta \cdot f) \cdot \beta \cdot \bar{S}}{1 - \beta \cdot (1 - \lambda)} dG(\epsilon) \\ &- (1 - p) \cdot G(\max\{\epsilon_s^{u,B}, \epsilon_s^{u,CP}\}) \cdot \beta \cdot F \\ &+ p \cdot \int_{\epsilon^p}^{\infty} \frac{z(\epsilon) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + (1 - \eta \cdot f) \cdot \beta \cdot \bar{S}}{1 - \beta \cdot (1 - \lambda)} dG(\epsilon) \\ &+ p \cdot \int_{\max\{\epsilon_s^{c,B}, \epsilon_s^{c,CP}\}}^{\epsilon^p} \frac{z(\epsilon) + \frac{u(c^c(\epsilon)) - u(b)}{u'(c^w)} - c^c(\epsilon) + (1 - \eta \cdot f) \cdot \beta \cdot \bar{S}}{1 - \beta \cdot (1 - \lambda)} dG(\epsilon) \\ &- (1 - p) \cdot G(\max\{\epsilon_s^{c,B}, \epsilon_s^{c,CP}\}) \cdot \beta \cdot F \end{aligned}$$

The FOC for working hours in unconstrained firms is:

$$\begin{aligned} \frac{\partial \mathcal{B}}{\partial h^u(\epsilon)} &= (1 - p) \cdot g(\epsilon) \cdot \left(\frac{\partial y(\epsilon, h^u(\epsilon))}{\partial h^u(\epsilon)} - \phi'(h^u(\epsilon)) \right) = 0 \\ \Leftrightarrow \quad \frac{\partial y(\epsilon, h^u(\epsilon))}{\partial h^u(\epsilon)} &= \phi'(h^u(\epsilon)) \end{aligned}$$

The FOC for working hours in constrained firms is:

$$\begin{aligned} \frac{\partial \mathcal{B}}{\partial h^c(\epsilon)} &= p \cdot g(\epsilon) \cdot \left(\frac{\partial y(\epsilon, h^c(\epsilon))}{\partial h^c(\epsilon)} - \phi'(h^c(\epsilon)) \right) \cdot \frac{u'(c^c(\epsilon))}{u'(c^w)} = 0 \\ \iff \frac{\partial y(\epsilon, h^c(\epsilon))}{\partial h^c(\epsilon)} &= \phi'(h^c(\epsilon)) \end{aligned}$$

Suppose that $\epsilon_s^{u,B} > \epsilon_s^{u,cp}$

$$\begin{aligned} \frac{\partial \mathcal{B}}{\partial \epsilon_s^{u,b}} &= -(1-p) \cdot g(\epsilon_s^{u,b}) \cdot \left[\frac{1}{1-\beta \cdot (1-\lambda)} \cdot \left(z(\epsilon_s^{u,b}) + \frac{u(c^w) - u(b)}{u'(c^w)} \right. \right. \\ &\quad \left. \left. - c^w + (\lambda - \eta f) \cdot \beta \cdot \bar{S} \right) + \beta \cdot F \right] = 0 \\ \iff z(\epsilon_s^{u,b}) &+ (1-\beta \cdot (1-\lambda)) \cdot \beta \cdot F + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + (\lambda - \eta f) \cdot \beta \cdot \bar{S} = 0 \end{aligned}$$

Insert free-entry Condition:

$$z(\epsilon_s^{u,b}) + (1-\beta \cdot (1-\lambda)) \cdot \beta \cdot F + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + \frac{\lambda - \eta f}{1-\eta} \cdot \left(\frac{k_v}{q} \right) = 0$$

Note that workers do not have a commitment problem $\epsilon_s^{u,B} > \epsilon_s^{u,cp}$, as workers would never quit under the insurance constraint of the firm:

$$V(\epsilon) - U = u(c^w) - u(b) + (\lambda - f) \cdot \beta \cdot (\bar{V} - U) > 0$$

Workers in unconstrained firms always have a positive surplus!

Suppose that $\epsilon_s^{c,B} \geq \epsilon_s^{c,cp}$

$$\begin{aligned} \frac{\partial \mathcal{B}}{\partial \epsilon_s^{c,B}} &= -(1-p) \cdot g(\epsilon_s^{c,B}) \cdot \left[\frac{1}{1-\beta \cdot (1-\lambda)} \cdot \left(z(\epsilon_s^{c,B}) + \frac{u(c^c(\epsilon_s^{c,B})) - u(b)}{u'(c^w)} \right. \right. \\ &\quad \left. \left. - c^c(\epsilon_s^{c,B}) + (\lambda - \eta f) \cdot \beta \cdot \bar{S} \right) + F \right] = 0 \\ \iff z(\epsilon_s^{c,B}) &+ (1-\beta \cdot (1-\lambda)) \cdot \beta \cdot F + \frac{u(c^c(\epsilon_s^{c,B})) - u(b)}{u'(c^w)} - c^c(\epsilon_s^{c,B}) + (\lambda - \eta f) \cdot \beta \cdot \bar{S} = 0 \end{aligned}$$

Insert free-entry condition:

$$z(\epsilon_s^{c,B}) + (1 - \beta \cdot (1 - \lambda)) \cdot \beta \cdot F + \frac{u(c^c(\epsilon_s^{c,B})) - u(b)}{u'(c^w)} - c^c(\epsilon_s^{cp}) + \frac{\lambda - \eta f}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

The participation constraint of workers can be written with free-entry condition as:

$$z(\epsilon_s^{c,cp}) + \frac{u(c^c(\epsilon_s^{c,cp})) - u(b)}{u'(c^w)} - c^c(\epsilon_s^{c,cp}) + \frac{(\lambda - \eta f)}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

Note that to avoid paying future lay-off taxes, firms would like workers to stay within the firm for negative surplus values. Thus, the worker decides to leave the firm unilaterally $\epsilon_s^{c,B} < \epsilon_s^{c,cp}$.

F.2 Job Creation and Wage Equation

The notation of this section follows Appendix H for lay-off taxes.

- (I) Value of an unconstrained firm after the idiosyncratic productivity shock has realized:

$$\begin{aligned} J^u(\epsilon) &= z(\epsilon) - c^w + \beta \cdot [\lambda \bar{J} + (1 - \lambda) \cdot J^u(\epsilon)] \\ \Leftrightarrow J^u(\epsilon) &= \frac{1}{1 - \beta \cdot (1 - \lambda)} [z(\epsilon) - c^w + \lambda \cdot \beta \cdot \bar{J}] \end{aligned}$$

- (II) Value of a constrained firm without binding constraints after the idiosyncratic productivity shock has realized:

$$\begin{aligned} J^c(\epsilon) &= z(\epsilon) - c^w + \beta \cdot [\lambda \bar{J} + (1 - \lambda) \cdot J^c(\epsilon)] \\ \Leftrightarrow J^c(\epsilon) &= \frac{1}{1 - \beta \cdot (1 - \lambda)} (z(\epsilon) - c^w + \lambda \cdot \beta \cdot \bar{J}) \end{aligned}$$

- (III) Value of a constrained firm with binding constraints after the idiosyncratic productivity shock has realized:

$$\begin{aligned} J^c(\epsilon) &= z(\epsilon) - c^w(\epsilon) + \beta \cdot [\lambda \bar{J} + (1 - \lambda) \cdot J^c(\epsilon)] \\ \Leftrightarrow J^c(\epsilon) &= \frac{1}{1 - \beta \cdot (1 - \lambda)} (z(\epsilon) - c^w(\epsilon) + \lambda \cdot \beta \cdot \bar{J}) \end{aligned}$$

- (IV) Value of a firm before the idiosyncratic productivity shock has realized:

$$\bar{J} = -\tau + (1 - p) \cdot \int_{\epsilon_s^u}^{\infty} J^u(\epsilon) dG(\epsilon) + p \cdot \int_{\epsilon_s^c}^{\infty} J^c(\epsilon) dG(\epsilon) - \rho \cdot \beta \cdot F$$

Inserting (I)-(III) into (IV) gives:

$$\Leftrightarrow \quad \bar{J} = -\tau + \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - \rho) \cdot z - (1 - p) \cdot (1 - \rho^u) \cdot c^w - p \cdot (1 - \rho^c) \cdot e^c \right. \\ \left. + (1 - p) \cdot \lambda \cdot \beta \cdot \bar{J} \right] - \rho \cdot \beta \cdot F$$

Here z denotes the average production (without distortions) and e^c denotes the average cost of a constrained worker for a firm. Both are defined in section H of the appendix.

(V) Value of an unconstrained worker after the idiosyncratic productivity shock has realized:

$$V^u(\epsilon) = u(c^w) + \beta \cdot [\lambda \bar{V} + (1 - \lambda) \cdot V^u(\epsilon)] \\ \Leftrightarrow \quad V^u(\epsilon) = \frac{1}{1 - \beta \cdot (1 - \lambda)} (u(c^w) + \lambda \cdot \beta \cdot \bar{V})$$

(VI) Value of a constrained worker without binding constraints after the idiosyncratic productivity shock has realized:

$$V^c(\epsilon) = u(c^w) + \beta \cdot [\lambda \bar{V} + (1 - \lambda) \cdot V^c(\epsilon)] \\ \Leftrightarrow \quad V^c(\epsilon) = \frac{1}{1 - \beta \cdot (1 - \lambda)} (u(c^w) + \lambda \cdot \beta \cdot \bar{V})$$

(VII) Value of a constrained worker with binding constraints after the idiosyncratic productivity shock has realized:

$$V^c(\epsilon) = u(c^w(\epsilon)) + \beta \cdot [\lambda \bar{V} + (1 - \lambda) \cdot V^c(\epsilon)] \\ \Leftrightarrow \quad V^c(\epsilon) = \frac{1}{1 - \beta \cdot (1 - \lambda)} (u(c^w(\epsilon)) + \lambda \cdot \beta \cdot \bar{V})$$

(VIII) Value of a worker before the idiosyncratic productivity shock has realized:

$$\bar{V} = (1 - p) \cdot \int_{\xi_s^u}^{\infty} V^u(\epsilon) dG(\epsilon) + p \cdot \int_{\xi_s^c}^{\infty} V^c(\epsilon) dG(\epsilon) + \rho \cdot U$$

Inserting (V)-(VII) into (VIII) gives:

$$\Leftrightarrow \quad \bar{V} = \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - p)(1 - \rho^u) \cdot u(c^w) + p \cdot (1 - \rho^c) \cdot u^c \right. \\ \left. + \beta \cdot [(1 - \rho) \cdot \lambda \cdot \beta \cdot \bar{V} + \rho \cdot U] \right]$$

u^c is defined as the average utility of a worker in a constrained firm. Its definition

can be found in appendix H.

(IX) Unemployment:

$$U = u(b) + \beta \cdot [f \cdot \bar{V} + (1 - f) \cdot U]$$

Next, we turn to calculating the joint surplus.

A) First, let us calculate the surplus of the worker after the idiosyncratic productivity shock has been realized:

$$\begin{aligned} V^i(\epsilon) - U &= u(c^i(\epsilon)) - u(b) + (\lambda - f) \cdot V^i(\epsilon) + (\lambda - f) \cdot \beta \cdot \bar{V} - (\lambda - f) \cdot \beta \cdot U \\ \Leftrightarrow V^i(\epsilon) - U &= u(c^i(\epsilon)) - u(b) + (\lambda - f) \cdot \beta \cdot (V^i(\epsilon) - U) + (\lambda - f) \cdot \beta \cdot (\bar{V} - U) \\ \Leftrightarrow V^i(\epsilon) - U &= \frac{1}{1 - \beta \cdot (1 - \lambda)} (u(c^i(\epsilon)) - u(b) + (\lambda - f) \cdot \beta \cdot (\bar{V} - U)) \end{aligned}$$

B) Next, we calculate the expected surplus of the worker, before the shocks have been realized:

$$\begin{aligned} \bar{V} - U &= (1 - \rho) \cdot \int_{\epsilon_s^u}^{\infty} (V^u(\epsilon) - U) dG(\epsilon) + p \cdot \int_{\epsilon_s^c}^{\infty} (V^c(\epsilon) - U) dG(\epsilon) \\ &= \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - \rho) \cdot (1 - \rho^u) \cdot (u(c^u) - u(b)) \right. \\ &\quad \left. + p \cdot (1 - \rho^c) \cdot (u(c^c) - u(b)) \right. \\ &\quad \left. + (1 - \rho) \cdot (\lambda - f) \cdot \beta \cdot (\bar{V} - U) \right] \end{aligned}$$

C) Next, we can calculate the joint surplus from the expected value of a worker for a firm and the expected surplus of the worker:

$$\begin{aligned} S &= \bar{J} + \frac{\bar{V} - U}{u'(c^u)} \\ &= -\tau + \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - \rho) \cdot z \right. \\ &\quad \left. + (1 - \rho) \cdot (1 - \rho^u) \cdot \left(\frac{u(c^u) - u(b)}{u'(c^u)} - c^u \right) \right. \\ &\quad \left. + p \cdot (1 - \rho^c) \cdot \left(\frac{u(c^c) - u(b)}{u'(c^u)} - c^c \right) \right. \\ &\quad \left. + (1 - \rho) \cdot \lambda \cdot \beta \cdot \bar{J} + (1 - \rho) \cdot (\lambda - f) \cdot \beta \cdot \frac{\bar{V} - U}{u'(c^u)} \right] - \rho \cdot \beta \cdot F \end{aligned}$$

Using the surplus splitting rule, we can rewrite the equation above as:

$$\begin{aligned}
S = & -\tau + \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - \rho) \cdot z \right. \\
& + (1 - \rho) \cdot (1 - \rho^u) \cdot \left(\frac{u(c^u) - u(b)}{u'(c^u)} - c^u \right) \\
& + p \cdot (1 - \rho^c) \cdot \left(\frac{u(c^c) - u(b)}{u'(c^u)} - e^c \right) \\
& \left. + (1 - \rho) \cdot (\lambda - \eta f) \cdot \beta \cdot S \right] - \rho \cdot \beta \cdot F
\end{aligned}$$

Next, we want to replace the tax in the surplus equation. We can do this by using the budget constraint of the government:

$$\begin{aligned}
n^s \cdot \tau &= -n^s \cdot \rho \cdot F + (1 - n) \cdot b \\
\Leftrightarrow \quad \tau &= -\rho \cdot F + \frac{1 - n}{n^s} \cdot b \\
\text{Insert } n^s &= \frac{\lambda}{1 - \rho} \cdot n \\
\Rightarrow \quad \tau &= \rho \cdot F + \frac{1}{\lambda} \cdot (1 - \rho) \cdot \frac{1 - n}{n} \cdot b
\end{aligned}$$

Inserting it into the equation for the joint surplus gives:

$$\begin{aligned}
S = & \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - \rho) \cdot \left(z - \frac{1 - n}{n} \cdot b \right) + (1 - p) \cdot (1 - \rho^u) \cdot \left(\frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right) \right. \\
& + p \cdot (1 - \rho^c) \cdot \left(\frac{u(c^c) - u(b)}{u'(c^w)} - e^c \right) + (1 - \rho) \cdot (\lambda - \eta f) \cdot \beta \cdot S \left. \right] \\
& - \frac{1}{\lambda} \cdot (1 - \rho) \cdot \frac{1 - n}{n} \cdot b + \rho \cdot (1 - \beta) \cdot F
\end{aligned}$$

Next, insert the free-entry condition: $\frac{k_v}{q} = \beta \cdot \bar{J}$

$$\begin{aligned}
\frac{1}{1-\eta} \cdot \frac{k_v}{q} = & \frac{\beta}{1-\beta \cdot (1-\lambda)} \cdot \left[(1-\rho) \cdot z \right. \\
& + (1-p) \cdot (1-\rho^u) \cdot \left(\frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right) \\
& + p \cdot (1-\rho^c) \cdot \left(\frac{u(c^c) - u(b)}{u'(c^w)} - e^c \right) \\
& \left. + (1-\rho) \cdot \left(\frac{\lambda - \eta f}{1-\eta} \cdot \frac{k_v}{q} \right) \right] \\
& - \frac{\beta}{\lambda} \cdot (1-\rho) \cdot \frac{1-n}{n} \cdot b + \rho \cdot \beta \cdot (1-\beta) \cdot F
\end{aligned}$$

The subsequent derivation of the wage equation is completely analogous to the derivation under STW regime described in Section G.2. The wage equation thus reads:

$$\begin{aligned}
(1-p) \cdot (1-\rho^u) \cdot (1-\eta) \cdot \left(\frac{u(c^w) - u(b)}{u'(c^w)} + \eta \cdot c^w \right) = \\
\eta \cdot [(1-\rho) \cdot z + (1-\rho) \cdot \theta \cdot k_v] \\
- \frac{1-\beta \cdot (1-\lambda)}{\lambda} \cdot (1-\rho) \cdot \frac{1-n}{n} \cdot b \\
+ \frac{1-\beta \cdot (1-\lambda)}{\lambda} \cdot \rho \cdot \beta \cdot (1-\beta) \cdot F \\
- p \cdot (1-\rho^c) \cdot (1-\eta) \cdot \left(\frac{u(c^c) - u(b)}{u'(c^w)} + \eta \cdot e^c \right)
\end{aligned}$$

G Equilibrium STW

G.1 Bargaining

Nash-Bargaining Problem:

$$\max_{\substack{w^u(\epsilon), w^c(\epsilon), w_{\text{stw}}^u(\epsilon), w_{\text{stw}}^c(\epsilon), \\ h^u(\epsilon), h^c(\epsilon), h_{\text{stw}}^u(\epsilon), h_{\text{stw}}^c(\epsilon), \\ \epsilon_s^u, \epsilon_s^c, \xi_s^u, \xi_s^c}} \bar{J}^{1-\eta} \cdot (\bar{V} - U)^\eta$$

Subject to:

1. Financial constraints of financially constrained firms:

$$\begin{aligned}
y(\epsilon, h(\epsilon)) - w^c(\epsilon) & \geq \beta \cdot [\lambda \cdot \bar{J} + (1-\lambda) \cdot J^c(\epsilon)] \\
y(\epsilon, h_{\text{stw}}(\epsilon)) - w_{\text{stw}}^c(\epsilon) & \geq \beta \cdot [\lambda \cdot \bar{J} + (1-\lambda) \cdot J_{\text{stw}}^c(\epsilon)]
\end{aligned}$$

2. Workers have a commitment problem:

$$\begin{aligned} U &\leq V^u(\epsilon), & U &\leq V_{\text{stw}}^u(\epsilon) \\ U &\leq V^c(\epsilon), & U &\leq V_{\text{stw}}^c(\epsilon) \end{aligned}$$

Second, we can integrate the commitment problem of the worker into the value functions for the firm and worker surplus. For $i \in \{\text{stw}, \text{no stw}\}$ and $j \in \{u, c\}$, we can reformulate the condition as:

$$u(c_i^j(\epsilon)) - u(b) + (\lambda - f) \cdot \beta \cdot (\bar{V} - U) \geq 0$$

Let $\epsilon_s^{j,\text{cp}}$ denote the threshold at which the worker wants to separate from a firm with STW support:

$$u(c_i^j(\epsilon_s^{j,\text{stw},\text{cp}})) - u(b) + (\lambda - f) \cdot \beta \cdot (\bar{V} - U) = 0$$

Likewise, we can determine the threshold at which workers leave firms without STW support, $\xi_s^{j,\text{cp}}$, as:

$$u(c_i^j(\xi_s^{j,\text{cp}})) - u(b) + (\lambda - f) \cdot \beta \cdot (\bar{V} - U) = 0$$

We can rewrite the value functions of the firm and the surplus of the worker as:

$$\begin{aligned} \bar{J} = & -\tau + (1-p) \cdot \left[\int_{\max\{\xi_s^{u,B}, \xi_s^{u,\text{cp}}, \epsilon_{\text{stw}}\}}^{\infty} \frac{1}{1 - \beta \cdot (1 - \lambda)} (z(\epsilon) - c^u(\epsilon) + \lambda\beta\bar{J}) dG(\epsilon) \right. \\ & \left. + \int_{\max\{\epsilon_s^{u,B}, \epsilon_s^{u,\text{cp}}, \epsilon_{\text{stw}}\}}^{\max\{\xi_s^{u,B}, \xi_s^{u,\text{cp}}, \epsilon_{\text{stw}}\}} \frac{1}{1 - \beta \cdot (1 - \lambda)} (z_{\text{stw}}(\epsilon) - c_{\text{stw}}^u(\epsilon) + \lambda\beta\bar{J}) dG(\epsilon) \right] \\ & + p \cdot \left[\int_{\max\{\xi_s^{c,B}, \xi_s^{c,\text{cp}}, \epsilon_{\text{stw}}\}}^{\infty} \frac{1}{1 - \beta \cdot (1 - \lambda)} (z(\epsilon) - c^c(\epsilon) + \lambda\beta\bar{J}) dG(\epsilon) \right. \\ & \left. + \int_{\max\{\epsilon_s^{c,B}, \epsilon_s^{c,\text{cp}}, \epsilon_{\text{stw}}\}}^{\max\{\xi_s^{c,B}, \xi_s^{c,\text{cp}}, \epsilon_{\text{stw}}\}} \frac{1}{1 - \beta \cdot (1 - \lambda)} (z_{\text{stw}}(\epsilon) - c_{\text{stw}}^c(\epsilon) + \lambda\beta\bar{J}) dG(\epsilon) \right] \end{aligned}$$

$$\begin{aligned}
& (\bar{V} - U) \\
&= (1-p) \cdot \left[\int_{\max\{\xi_s^{u,B}, \xi_s^{u,CP}, \epsilon_{stw}\}}^{\infty} \frac{1}{1-\beta \cdot (1-\lambda)} (u(c^u(\epsilon)) - u(b) + \lambda\beta(\bar{V} - U)) dG(\epsilon) \right. \\
&\quad \left. + \int_{\max\{\epsilon_s^{u,B}, \epsilon_s^{u,CP}\}}^{\max\{\xi_s^{u,B}, \xi_s^{u,CP}, \epsilon_{stw}\}} \frac{1}{1-\beta \cdot (1-\lambda)} (u(c_{stw}^u(\epsilon)) + s_{stw}(\bar{h} - h_{stw}(\epsilon)) - u(b) + \lambda\beta(\bar{V} - U)) dG(\epsilon) \right] \\
&+ p \cdot \left[\int_{\max\{\xi_s^{c,B}, \xi_s^{c,CP}, \epsilon_{stw}\}}^{\infty} \frac{1}{1-\beta \cdot (1-\lambda)} (u(c^c(\epsilon)) - u(b) + \lambda\beta(\bar{V} - U)) dG(\epsilon) \right. \\
&\quad \left. + \int_{\max\{\epsilon_s^{c,B}, \epsilon_s^{c,CP}\}}^{\max\{\xi_s^{c,B}, \xi_s^{c,CP}, \epsilon_{stw}\}} \frac{1}{1-\beta \cdot (1-\lambda)} (u(c_{stw}^c(\epsilon)) + s_{stw}(\bar{h} - h_{stw}(\epsilon)) - u(b) + \lambda\beta(\bar{V} - U)) dG(\epsilon) \right]
\end{aligned}$$

Note that $\xi_s^{u,B}, \xi_s^{c,B}, \epsilon_s^{u,B}$ and $\epsilon_s^{c,B}$ denote the separation thresholds at bargaining outcome.

Note that we can rewrite the problem so that we optimize over consumption equivalents instead of salaries. $c_{stw}^i(\epsilon)$ denotes the consumption equivalent paid from the firm to the worker on STW. $c^i(\epsilon)$ is the consumption equivalent consumed by the worker.

$$\max_{\substack{c^u(\epsilon), c^c(\epsilon), c_{stw}^u(\epsilon), c_{stw}^c(\epsilon), \\ h^u(\epsilon), h^c(\epsilon), h_{stw}^u(\epsilon), h_{stw}^c(\epsilon), \\ \xi_s^{u,B}, \xi_s^{c,B}, \epsilon_s^{u,B}, \epsilon_s^{c,B}}} (\bar{J})^{1-\eta} \cdot (\bar{V} - U)^\eta$$

Financial constraints of financially constrained firms

$$\begin{aligned}
y(\epsilon, h(\epsilon)) - w^c(\epsilon) &\geq \beta \cdot [\lambda \cdot \bar{J} + (1-\lambda) \cdot J^c(\epsilon)] \\
y(\epsilon, h_{stw}(\epsilon)) - w_{stw}^c(\epsilon) &\geq \beta \cdot [\lambda \cdot \bar{J} + (1-\lambda) \cdot J_{stw}^c(\epsilon)]
\end{aligned}$$

Set up Kuhn-Tucker Conditions:

$$\begin{aligned}
& (\bar{J})^\eta \cdot (\bar{V} - U)^{1-\eta} - \int_0^\infty \mathcal{M}(\epsilon) [z(\epsilon) - c^c(\epsilon) + \beta \cdot [\lambda \cdot \bar{J} + (1-\lambda) \cdot J^c(\epsilon)]] dG(\epsilon) \\
& - \int_0^\infty \mathcal{M}_{stw}(\epsilon) [z_{stw}(\epsilon) - c_{stw}^c(\epsilon) + \beta \cdot [\lambda \cdot \bar{J} + (1-\lambda) \cdot J_{stw}^c(\epsilon)]] dG(\epsilon)
\end{aligned}$$

With Kuhn-Tucker conditions for a maximum:

$$\begin{aligned}
\text{(A)} \quad & \text{(i) } \mathcal{M}(\epsilon) \leq 0 \\
& \text{(ii) } \mathcal{M}(\epsilon) [z(\epsilon) - c^c(\epsilon) + \beta \cdot [\lambda \cdot \bar{J} + (1-\lambda) \cdot J^c(\epsilon)]] = 0 \\
\text{(B)} \quad & \text{(i) } \mathcal{M}_{stw}(\epsilon) \leq 0 \\
& \text{(ii) } \mathcal{M}_{stw}(\epsilon) [z_{stw}(\epsilon) - c_{stw}^c(\epsilon) + \beta \cdot [\lambda \cdot \bar{J} + (1-\lambda) \cdot J_{stw}^c(\epsilon)]] = 0
\end{aligned}$$

FOC for $c^u(\epsilon)$:

$$\begin{aligned}\frac{\partial \mathcal{B}}{\partial c^u(\epsilon)} &= -(1-\eta) \cdot (1-p) \cdot g(\epsilon) \left(\frac{\bar{V} - U}{\bar{J}} \right)^\eta \\ &\quad + \eta \cdot (1-p) \cdot g(\epsilon) \cdot u'(c^u(\epsilon)) \left(\frac{\bar{J}}{\bar{V} - U} \right)^{1-\eta} = 0\end{aligned}$$

Unconstrained firms want to insure workers against idiosyncratic productivity shocks, outside STW:

$$\Leftrightarrow \quad \frac{1-\eta}{\eta} \cdot \frac{\bar{V} - U}{\bar{J}} = u'(c^u(\epsilon)) \quad \Rightarrow \quad u'(c^u(\epsilon)) = u'(c^u(\epsilon')) = u'(c^u)$$

FOC for $c_{\text{stw}}^u(\epsilon)$:

$$\begin{aligned}\frac{\partial \mathcal{B}}{\partial c_{\text{stw}}^u(\epsilon)} &= -(1-\eta)(1-p) \cdot g(\epsilon) \left(\frac{\bar{V} - U}{\bar{J}} \right)^\eta \\ &\quad + \eta \cdot (1-p) \cdot g(\epsilon) \cdot u'(c_{\text{stw}}^u(\epsilon)) \cdot \eta \cdot \left(\frac{\bar{J}}{\bar{V} - U} \right)^{1-\eta} = 0\end{aligned}$$

Unconstrained firms want to insure workers against idiosyncratic productivity shocks, also on STW:

$$\begin{aligned}\Leftrightarrow \quad &\frac{1-\eta}{\eta} \cdot \frac{\bar{V} - U}{\bar{J}} = u'(c^u(\epsilon)) \\ \Rightarrow \quad &u'(c_{\text{stw}}^u(\epsilon)) = u'(c_{\text{stw}}^u(\epsilon')) = u'(c^w)\end{aligned}$$

FOC for $c^c(\epsilon)$:

$$\begin{aligned}\frac{\partial \mathcal{B}}{\partial c^c(\epsilon)} &= -(1-p) \cdot g(\epsilon) \cdot (1-\eta) \cdot \left(\frac{\bar{V} - U}{\bar{J}} \right)^\eta \\ &\quad + (1-p) \cdot g(\epsilon) \cdot u'(c^c(\epsilon)) \cdot \eta \cdot \left(\frac{\bar{J}}{\bar{V} - U} \right)^{1-\eta} + \mathcal{M}(\epsilon) \\ &\stackrel{!}{=} 0\end{aligned}$$

Insert the surplus splitting rule:

$$\begin{aligned}
& - (1-p) \cdot g(\epsilon) \cdot \left(\frac{\eta}{1-\eta} \cdot u'(c^w) \right)^\eta \\
& + (1-p) \cdot g(\epsilon) \cdot u'(c^c(\epsilon)) \cdot \eta \cdot \left(\frac{1-\eta}{\eta} \cdot \frac{1}{u'(c^w)} \right) + \mathcal{M}(\epsilon) \stackrel{!}{=} 0
\end{aligned}$$

$$\Longleftrightarrow (1-p) \cdot g(\epsilon) \cdot \eta \cdot (u'(c^c(\epsilon)) - u'(c^w)) = -\mathcal{M}(\epsilon) \cdot \left(u'(c^w) \cdot \frac{\eta}{1-\eta} \right)^{1-\eta}$$

Note: If $c^c(\epsilon) < u'(c^w)$, then the RHS of the equation is positive.

Thus, firms and workers gain joint surplus until $c^c(\epsilon) = c^w$.

If

$$z(\epsilon) - c^w + \beta \cdot [\lambda \cdot \bar{J} + (1-\lambda) \cdot J^c(\epsilon)] \geq 0,$$

then the constraint is non-binding and $\mathcal{M}(\epsilon) = 0$. ✓

If

$$z(\epsilon) - c^w + \beta \cdot [\lambda \cdot \bar{J} + (1-\lambda) \cdot J^c(\epsilon)] < 0,$$

then the constraint is binding and $\mathcal{M}(\epsilon) < 0$. ✓

Thus, it is optimal for the firm to pay as much as it can:

$$J^c(\epsilon) = z(\epsilon) - c^c(\epsilon) + \beta \cdot [\lambda \cdot \bar{J} + (1-\lambda) \cdot J^c(\epsilon)] = 0$$

$$\Longleftrightarrow c^c(\epsilon) = z(\epsilon) + \lambda \cdot \beta \cdot \bar{J}$$

Using the same arguments, we get that under STW

$$c_{\text{stw}}(\epsilon) = c^w \quad \text{if the financial constraint is non-binding,}$$

and

$$c_{\text{stw}}(\epsilon) = \epsilon_{\text{stw}}(\epsilon) + s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon)) + \lambda \cdot \beta \cdot \bar{J} \quad \text{when it is binding.}$$

Using the surplus splitting rule, we can simplify the Nash-Bargaining problem to:

$$\max_{h^u(\epsilon), h^c(\epsilon), h_{\text{stw}}^u(\epsilon), h_{\text{stw}}^c(\epsilon), \xi_S^u, \xi_S^c, \xi_{S^c}^u, \xi_{S^c}^c} (1-\eta)^{1-\eta} \cdot (u'(c^w) \cdot \eta)^\eta \cdot \bar{S}$$

That is, we just have to maximize the joint surplus:

$$\begin{aligned}
\bar{S} = & -\tau \\
& + (1-p) \cdot \int_{\max\{\xi_s^{u,B}, \xi_s^{u,cp}, \epsilon_{stw}\}}^{\infty} \frac{1}{1-\beta \cdot (1-\lambda)} \left(z(\epsilon) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + (1-\eta \cdot f) \cdot \beta \cdot \bar{S} \right) dG(\epsilon) \\
& + (1-p) \cdot \int_{\max\{\epsilon_s^{u,B}, \epsilon_s^{u,cp}\}}^{\max\{\epsilon_s^{u,B}, \epsilon_s^{u,cp}, \epsilon_{stw}\}} \frac{1}{1-\beta \cdot (1-\lambda)} \left(z(\epsilon) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right. \\
& \quad \left. + s_{stw}(\bar{h} - h_{stw}(\epsilon)) + (1-\eta \cdot f) \cdot \beta \cdot \bar{S} \right) dG(\epsilon) \\
& + p \cdot \int_{\epsilon^p}^{\infty} \frac{1}{1-\beta \cdot (1-\lambda)} \left(z(\epsilon) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + (1-\eta \cdot f) \cdot \beta \cdot \bar{S} \right) dG(\epsilon) \\
& + p \cdot \int_{\max\{\xi_s^c, \xi_s^{c,cp}, \epsilon_{stw}\}}^{\epsilon^p} \frac{1}{1-\beta \cdot (1-\lambda)} \left(z(\epsilon) + \frac{u(c^c(\epsilon)) - u(b)}{u'(c^w)} - c^c(\epsilon) + (1-\eta \cdot f) \cdot \beta \cdot \bar{S} \right) dG(\epsilon) \\
& + p \cdot \int_{\max\{\epsilon_s^c, \epsilon_s^{c,cp}\}}^{\max\{\epsilon_s^c, \epsilon_s^{c,cp}, \epsilon_{stw}\}} \frac{1}{1-\beta \cdot (1-\lambda)} \left(z_{stw}(\epsilon) + \frac{u(c_{stw}^c(\epsilon)) - u(b)}{u'(c^w)} \right. \\
& \quad \left. - c^c(\epsilon) + (1-\eta \cdot f) \cdot \beta \cdot \bar{S} \right) dG(\epsilon)
\end{aligned}$$

Note that without financial constraints, the firm smooths the consumption equivalent consumed by the worker:

$$\begin{aligned}
c^w &= c_{stw}^u(\epsilon) = c_{stw}^u(\epsilon) + s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon)) \\
\Leftrightarrow \quad c_{stw}^u &= c^w - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon))
\end{aligned}$$

STW makes it less expensive to smooth consumption equivalents consumed by the worker.

The FOC for working hours in unconstrained firms outside STW is:

$$\begin{aligned}
\frac{\partial \mathcal{B}}{\partial h^u(\epsilon)} &= (1-p) \cdot g(\epsilon) \cdot \left(\frac{\partial y(\epsilon, h^u(\epsilon))}{\partial h^u(\epsilon)} - \phi'(h^u(\epsilon)) \right) = 0 \\
\Leftrightarrow \quad \frac{\partial y(\epsilon, h^u(\epsilon))}{\partial h^u(\epsilon)} &= \phi'(h^u(\epsilon))
\end{aligned}$$

The FOC for working hours in constrained firms *outside* STW is:

$$\begin{aligned}
\frac{\partial \mathcal{B}}{\partial h^c(\epsilon)} &= p \cdot g(\epsilon) \cdot \left(\frac{\partial y(\epsilon, h^c(\epsilon))}{\partial h^c(\epsilon)} - \phi'(h^c(\epsilon)) \right) \cdot \frac{u'(c^c(\epsilon))}{u'(c^w)} = 0 \\
\Leftrightarrow \quad \frac{\partial y(\epsilon, h^c(\epsilon))}{\partial h^c(\epsilon)} &= \phi'(h^c(\epsilon))
\end{aligned}$$

The FOC for working hours in unconstrained firms *on* STW is:

$$\begin{aligned}\frac{\partial \mathcal{B}}{\partial h_{\text{stw}}^u(\epsilon)} &= (1-p) \cdot g(\epsilon) \cdot \left(\frac{\partial y(\epsilon, h_{\text{stw}}^u(\epsilon))}{\partial h_{\text{stw}}^u(\epsilon)} - \phi'(h_{\text{stw}}^u(\epsilon)) - s_{\text{stw}} \right) = 0 \\ \Leftrightarrow \quad \frac{\partial y(\epsilon, h_{\text{stw}}^u(\epsilon))}{\partial h_{\text{stw}}^u(\epsilon)} &= \phi'(h_{\text{stw}}^u(\epsilon)) + s_{\text{stw}}\end{aligned}$$

The FOC for working hours in constrained firms *on* STW is:

$$\begin{aligned}\frac{\partial \mathcal{B}}{\partial h^c(\epsilon)} &= p \cdot g(\epsilon) \cdot \left(\frac{\partial y(\epsilon, h^c(\epsilon))}{\partial h^c(\epsilon)} - \phi'(h^c(\epsilon)) - s_{\text{stw}} \right) \cdot \frac{u'(c^c(\epsilon))}{u'(c^w)} = 0 \\ \Leftrightarrow \quad \frac{\partial y(\epsilon, h^c(\epsilon))}{\partial h^c(\epsilon)} &= \phi'(h^c(\epsilon)) + s_{\text{stw}}\end{aligned}$$

Suppose that

$$\max\{\xi_s^{u,B}, \xi_s^{u,\text{cp}}, \epsilon_{\text{stw}}\} = \xi_s^{u,B}$$

Then the FOC for the separation threshold of the unconstrained firm without STW support is:

$$\begin{aligned}\frac{\partial \mathcal{B}}{\partial \xi_s^{u,B}} &= -(1-p) \cdot g(\xi_s^{u,B}) \cdot \frac{1}{1 - \beta \cdot (1 - \lambda)} \left(z(\xi_s^{u,B}) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + (\lambda - \eta f) \cdot \beta \cdot \bar{S} \right) = 0 \\ \Leftrightarrow \quad z(\xi_s^{u,B}) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + (\lambda - \eta f) \cdot \beta \cdot \bar{S} &= 0\end{aligned}$$

Insert free-entry Condition:

$$z(\xi_s^{u,B}) + z(\xi_s^{u,B}) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + \frac{(\lambda - \eta f)}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

Note that $\xi_s^{u,B} > \xi_s^{u,\text{cp}}$ must hold, as workers would never quit under the insurance constraint of the firm:

$$V(\epsilon) - U = u(c^w) - u(b) + (\lambda - f) \cdot \beta \cdot (\bar{V} - U) > 0$$

It always gets positive surplus!

Suppose that

$$\max\{\xi_s^{c,B}, \xi_s^{c,\text{cp}}, \epsilon_{\text{stw}}\} = \xi_s^{c,B}$$

Then the FOC for the separation threshold of the unconstrained firm without STW

support is:

$$\begin{aligned} \frac{\partial \mathcal{B}}{\partial \xi_s^{c,B}} &= -(1-p) \cdot g(\xi_s^{c,B}) \cdot \left[\frac{1}{1-\beta \cdot (1-\lambda)} \cdot \left(z(\xi_s^{c,B}) + \frac{u(c^c(\xi_s^{c,B})) - u(b)}{u'(c^w)} \right. \right. \\ &\quad \left. \left. - c^c(\xi_s^{c,B}) + (\lambda - \eta f) \cdot \beta \cdot \bar{S} \right) \right] = 0 \\ \iff z(\xi_s^{c,B}) + \frac{u(c^c(\xi_s^{c,B})) - u(b)}{u'(c^w)} - c^c(\xi_s^{c,B}) + (\lambda - \eta f) \cdot \beta \cdot \bar{S} &= 0 \end{aligned}$$

Insert free-entry condition:

$$z(\xi_s^{c,B}) + \frac{u(c^c(\xi_s^{c,B})) - u(b)}{u'(c^w)} - c^c(\xi_s^{c,B}) + \frac{(\lambda - \eta f)}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

The participation constraint of workers can be written with free-entry condition as:

$$z(\xi_s^{c,\text{cp}}) + \frac{u(c^c(\xi_s^{c,\text{cp}})) - u(b)}{u'(c^w)} - c^c(\xi_s^{c,\text{cp}}) + \frac{(\lambda - \eta f)}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

Note that these are the same conditions. This implies that given the inability to insure workers against idiosyncratic productivity shocks, separations for a constrained firm without access to STW are efficient.

Suppose that

$$\max\{\epsilon_s^{u,B}, \epsilon_s^{u,\text{cp}}, \epsilon_{\text{stw}}\} = \epsilon_s^{u,B}$$

Then the FOC for the separation threshold of the unconstrained firm with STW support is:

$$\begin{aligned} \frac{\partial \mathcal{B}}{\partial \epsilon_s^{u,B}} &= -(1-p) \cdot g(\epsilon_s^{u,B}) \cdot \left[\frac{1}{1-\beta \cdot (1-\lambda)} \cdot \left(z_{\text{stw}}(\epsilon_s^{u,B}) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right. \right. \\ &\quad \left. \left. + s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^{u,B})) + (\lambda - \eta f) \cdot \beta \cdot \bar{S} \right) \right] = 0 \end{aligned}$$

$$\iff z_{\text{stw}}(\epsilon_s^{u,B}) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^{u,B})) + (\lambda - \eta f) \cdot \beta \cdot \bar{S} = 0$$

Insert free-entry Condition:

$$z_{\text{stw}}(\epsilon_s^{u,B}) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + \frac{\lambda - \eta f}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

Note that $\epsilon_s^{u,B} > \epsilon_s^{u,\text{cp}}$ must hold, as workers would never quit under the insurance con-

straint of the firm:

$$V(\epsilon) - U = u(c^w) - u(b) + (\lambda - f) \cdot \beta \cdot (\bar{V} - U) > 0$$

It always gets positive surplus!

Suppose that

$$\max\{\epsilon_s^{c,B}, \epsilon_s^{c,CP}, \epsilon_{\text{stw}}\} = \epsilon_s^{c,B}$$

Then the FOC for the separation threshold of the constrained firm with STW support is:

$$\begin{aligned} \frac{\partial \mathcal{B}}{\partial \epsilon_s^{c,B}} &= -(1-p) \cdot g(\epsilon_s^{c,B}) \cdot \left[\frac{1}{1 - \beta \cdot (1 - \lambda)} \cdot \left(z_{\text{stw}}(\epsilon_s^{c,B}) + \frac{u(c_{\text{stw}}^c(\epsilon_s^{c,B})) - u(b)}{u'(c^w)} \right. \right. \\ &\quad \left. \left. - c_{\text{stw}}^c(\epsilon_s^{c,B}) + (\lambda - \eta f) \cdot \beta \cdot \bar{S} \right) \right] = 0 \\ \iff z(\epsilon_s^{c,B}) + \frac{u(c_{\text{stw}}^c(\epsilon_s^{c,B})) - u(b)}{u'(c^w)} - c_{\text{stw}}^c(\epsilon_s^{c,B}) + (\lambda - \eta f) \cdot \beta \cdot \bar{S} &= 0 \end{aligned}$$

Insert free-entry condition:

$$z_{\text{stw}}(\epsilon_s^{c,B}) + \frac{u(c_{\text{stw}}^c(\epsilon_s^{c,B})) - u(b)}{u'(c^w)} - c_{\text{stw}}^c(\epsilon_s^{c,B}) + \frac{\lambda - \eta f}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

The participation constraint of workers can be written with free-entry condition as:

$$z_{\text{stw}}(\epsilon_s^{c,CP}) + \frac{u(c_{\text{stw}}^c(\epsilon_s^{c,CP})) - u(b)}{u'(c^w)} - c_{\text{stw}}^c(\epsilon_s^{c,CP}) + \frac{\lambda - \eta f}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

Note that these are the same conditions. This implies that, given the inability to insure workers against idiosyncratic productivity shocks, separations for a constrained firm with access to STW are efficient.

G.2 Job Creation and Wage Equation

This section derives the job creation and the equation for STW. It follows its notation part H of the appendix.

- (I) Value of an unconstrained firm outside STW after the idiosyncratic productivity shock has realized:

$$\begin{aligned} J^u(\epsilon) &= z(\epsilon) - c^w + \beta \cdot [\lambda \bar{J} + (1 - \lambda) J^u(\epsilon)] \\ \Leftrightarrow J^u(\epsilon) &= \frac{1}{1 - \beta \cdot (1 - \lambda)} (z(\epsilon) - c^w + \lambda \beta \bar{J}) \end{aligned}$$

(II) Value of an unconstrained firm on STW after the idiosyncratic productivity shock has realized:

$$J_{\text{stw}}^u(\epsilon) = z_{\text{stw}}(\epsilon) + s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon)) - c^w + \beta [\lambda \bar{J} + (1 - \lambda) J_{\text{stw}}^u(\epsilon)]$$

$$\Leftrightarrow J_{\text{stw}}^u(\epsilon) = \frac{1}{1 - \beta \cdot (1 - \lambda)} (z_{\text{stw}}(\epsilon) - c^w + \lambda \beta \bar{J})$$

(III) Value of a constrained firm outside STW with non-binding constraints after the idiosyncratic productivity shock has realized:

$$J^c(\epsilon) = z(\epsilon) - c^w + \beta \cdot [\lambda \bar{J} + (1 - \lambda) J^c(\epsilon)]$$

$$\Leftrightarrow J^c(\epsilon) = \frac{1}{1 - \beta \cdot (1 - \lambda)} (z(\epsilon) - c^w + \lambda \beta \bar{J})$$

(IV) Value of a constrained firm outside STW with binding constraints after the idiosyncratic productivity shock has realized:

$$J^c(\epsilon) = z(\epsilon) - c^w(\epsilon) + \beta [\lambda \bar{J} + (1 - \lambda) J^c(\epsilon)]$$

$$\Leftrightarrow J^c(\epsilon) = \frac{1}{1 - \beta \cdot (1 - \lambda)} (z(\epsilon) - c^w(\epsilon) + \lambda \beta \bar{J})$$

(V) Value of a constrained firm on STW after the idiosyncratic productivity shock has realized:

$$J_{\text{stw}}^c(\epsilon) = z_{\text{stw}}(\epsilon) - c_{\text{stw}}^w(\epsilon) + \beta \cdot [\lambda J + (1 - \lambda) J_{\text{stw}}^c(\epsilon)]$$

$$\Leftrightarrow J_{\text{stw}}^c(\epsilon) = \frac{1}{1 - \beta \cdot (1 - \lambda)} (z_{\text{stw}}(\epsilon) - c_{\text{stw}}^w(\epsilon) + \lambda \beta J)$$

(VI) Value of a firm before the idiosyncratic productivity shock has realized:

$$\bar{J} = -\tau + (1 - p) \cdot \left(\int_{\epsilon_{\text{stw}}}^{\infty} J^u(\epsilon) dG(\epsilon) + \int_{\epsilon_s^u}^{\epsilon_{\text{stw}}} J_{\text{stw}}^u(\epsilon) dG(\epsilon) \right)$$

$$+ p \cdot \left(\int_{\max\{\epsilon_{\text{stw}}, \epsilon_s^c\}}^{\infty} J^c(\epsilon) dG(\epsilon) + \int_{\epsilon_s^c}^{\max\{\epsilon_{\text{stw}}, \epsilon_s^c\}} J_{\text{stw}}^c(\epsilon) dG(\epsilon) \right)$$

Inserting (I) - (IV) into (V) gives:

$$\begin{aligned}
\bar{J} = & -\tau \\
& + \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - \rho) \cdot (z - \Omega) \right. \\
& - (1 - p) \cdot (1 - \rho^u) \cdot \left(c^w - \int_{\epsilon_s^u}^{\epsilon_{stw}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \right) \\
& - p \cdot (1 - \rho^c) \cdot \left(e^c - \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \right) \\
& \left. + (1 - \rho) \cdot \lambda \cdot \beta \cdot \bar{J} \right]
\end{aligned}$$

Here z denotes the average production (without distortions) and ec denotes the average cost of a constrained worker for a firm. Both are defined in section D of the appendix.

(VII) Value of an unconstrained worker outside STW after the idiosyncratic productivity shock has realized:

$$\begin{aligned}
V^u(\epsilon) &= u(c^w) + \beta \cdot [\lambda \bar{V} + (1 - \lambda) V^u(\epsilon)] \\
\Leftrightarrow V^u(\epsilon) &= \frac{1}{1 - \beta \cdot (1 - \lambda)} (u(c^w) + \lambda \beta \bar{V})
\end{aligned}$$

(VIII) Value of an unconstrained worker on STW after the idiosyncratic productivity shock has realized:

$$\begin{aligned}
V_{stw}^u(\epsilon) &= u(c^w) + \beta \cdot [\lambda \bar{V} + (1 - \lambda) V_{stw}^u(\epsilon)] \\
\Leftrightarrow V_{stw}^u(\epsilon) &= \frac{1}{1 - \beta \cdot (1 - \lambda)} (u(c^w) + \lambda \beta \bar{V})
\end{aligned}$$

(IX) Value of a constrained worker outside STW with non-binding constraints after the idiosyncratic productivity shock has realized:

$$\begin{aligned}
V^c(\epsilon) &= u(c^w) + \beta \cdot [\lambda \bar{V} + (1 - \lambda) V^c(\epsilon)] \\
\Leftrightarrow V^c(\epsilon) &= \frac{1}{1 - \beta \cdot (1 - \lambda)} (u(c^w) + \lambda \beta \bar{V})
\end{aligned}$$

(X) Value of a constrained worker outside STW with binding constraints after the id-

iosyncratic productivity shock has realized:

$$\begin{aligned} V^c(\epsilon) &= u(c^w(\epsilon)) + \beta \cdot [\lambda \bar{V} + (1 - \lambda) V^c(\epsilon)] \\ \Leftrightarrow V^c(\epsilon) &= \frac{1}{1 - \beta \cdot (1 - \lambda)} (u(c^w(\epsilon)) + \lambda \beta \bar{V}) \end{aligned}$$

(XI) Value of a constrained worker on STW after the idiosyncratic productivity shock has realized:

$$\begin{aligned} V_{\text{stw}}^c(\epsilon) &= u(c_{\text{stw}}(\epsilon)) + \beta \cdot [\lambda \bar{V} + (1 - \lambda) V_{\text{stw}}^c(\epsilon)] \\ \Leftrightarrow V_{\text{stw}}^c(\epsilon) &= \frac{1}{1 - \beta \cdot (1 - \lambda)} (u(c_{\text{stw}}(\epsilon)) + \lambda \beta \bar{V}) \end{aligned}$$

(XII) Value of a worker before the idiosyncratic productivity shock has realized:

$$\begin{aligned} \bar{V} &= (1 - p) \cdot \left(\int_{\epsilon_{\text{stw}}}^{\infty} V^u(\epsilon) dG(\epsilon) \right. \\ &\quad \left. + \int_{\epsilon_s^u}^{\epsilon_{\text{stw}}} V_{\text{stw}}^u(\epsilon) dG(\epsilon) \right) \\ &\quad + p \cdot \left(\int_{\epsilon_p}^{\infty} V^c(\epsilon) dG(\epsilon) \right. \\ &\quad \left. + \int_{\max\{\xi_s^c, \epsilon_{\text{stw}}\}}^{\epsilon_p} V^c(\epsilon) dG(\epsilon) \right. \\ &\quad \left. + \int_{\epsilon_s^c}^{\max\{\epsilon_s^c, \epsilon_{\text{stw}}\}} V_{\text{stw}}^c(\epsilon) dG(\epsilon) \right) \\ &\quad + \rho \cdot U \end{aligned}$$

Inserting (VII) - (XI) into (XII) gives:

$$\begin{aligned} \bar{V} &= \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - p)(1 - \rho^u) \cdot u(c^w) + p \cdot (1 - \rho^c) \cdot u^c \right. \\ &\quad \left. + (1 - \rho) \cdot \lambda \cdot \beta \cdot \bar{V} + \rho \cdot U \right] \end{aligned}$$

Here u^c denotes the average utility of a constrained worker for a firm. Both are defined in section H of the appendix.

(XIII) Unemployment:

$$U = u(b) + \beta \cdot [f \cdot \bar{V} + (1 - f) \cdot U]$$

Next, we want to calculate the joint surplus of firms and workers.

(A) The surplus of the worker after the idiosyncratic productivity shock has realized is:

$$\begin{aligned}
V_i^j(\epsilon) - U &= u(c_i^j(\epsilon)) - u(b) + (\lambda - f) \cdot V_i^j(\epsilon) + (\lambda - f) \cdot \beta \cdot \bar{V} - (\lambda - f) \cdot \beta \cdot U \\
\Leftrightarrow V_i^j(\epsilon) - U &= u(c_i^j(\epsilon)) - u(b) + (\lambda - f) \cdot \beta \cdot (V_i^j(\epsilon) - U) + (\lambda - f) \cdot \beta \cdot (\bar{V} - U) \\
\Leftrightarrow V_i^j(\epsilon) - U &= u(c_i^j(\epsilon)) - u(b) + (\lambda - f) \cdot (V_i^j(\epsilon) - U) + (\lambda - f) \cdot \beta \cdot (\bar{V} - U) \\
\Leftrightarrow V_i^j(\epsilon) - U &= \frac{1}{1 - \beta \cdot (1 - \lambda)} \left(u(c_i^j(\epsilon)) - u(b) + (\lambda - f) \cdot \beta \cdot (\bar{V} - U) \right)
\end{aligned}$$

for $i \in \{\text{stw}, \text{no stw}\}$ and $j \in \{u, c\}$.

(B) The surplus of the worker before shock realizations are known:

$$\begin{aligned}
\bar{V} - U &= (1 - p) \cdot \left(\int_{\epsilon_{\text{stw}}}^{\infty} V^u(\epsilon) - U dG(\epsilon) + \int_{\epsilon_s^u}^{\epsilon_{\text{stw}}} V_{\text{stw}}^u(\epsilon) - U dG(\epsilon) \right) \\
&+ p \cdot \left(\int_{\epsilon_p}^{\infty} V^c(\epsilon) - U dG(\epsilon) + \int_{\max\{\epsilon_s^c, \epsilon_{\text{stw}}\}}^{\epsilon_p} V^c(\epsilon) - U dG(\epsilon) \right. \\
&\left. + \int_{\epsilon_s^c}^{\max\{\epsilon_s^c, \epsilon_{\text{stw}}\}} V_{\text{stw}}^c(\epsilon) - U dG(\epsilon) \right)
\end{aligned}$$

Inserting A into B gives:

$$\begin{aligned}
\bar{V} - U &= \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - p)(1 - \rho^u) \cdot (u(c^w) - u(b)) \right. \\
&+ p \cdot (1 - \rho^c) \cdot (u^c - u(b)) \\
&\left. + (\lambda - f) \cdot \beta \cdot (\bar{V} - U) \right]
\end{aligned}$$

(C) Finally, we can calculate the joint surplus before shock realizations are known:

$$\begin{aligned}
S &= J + \frac{\bar{V} - U}{u'(c^w)} \\
&= -\tau + \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - \rho)(1 - \rho^u) \cdot \left(\frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right. \right. \\
&\quad \left. \left. + \frac{1}{1 - \rho^u} \int_{\epsilon_s^u}^{\epsilon_{\text{stw}}} s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon)) dG(\epsilon) \right) \right. \\
&\quad \left. + p(1 - \rho^c) \cdot \left(\frac{u^c - u(b)}{u'(c^w)} - e^c \right. \right. \\
&\quad \left. \left. + \frac{1}{1 - \rho^c} \int_{\epsilon_s^c}^{\max\{\epsilon_{\text{stw}}, \epsilon_s^c\}} s_{\text{stw}} (\bar{h} - h_{\text{stw}}(\epsilon)) dG(\epsilon) \right) \right. \\
&\quad \left. + (1 - \rho)\lambda\beta J + (1 - \rho)(\lambda - f) \cdot \beta \cdot \frac{\bar{V} - U}{u'(c^w)} \right]
\end{aligned}$$

Next, we start deriving the job-creation condition. Inserting the surplus splitting rule

$$J = \eta \cdot S, \quad \frac{\bar{V} - U}{u'(c^w)} = (1 - \eta) \cdot S$$

into the equation for the joint surplus gives:

$$\begin{aligned} S &= J + \frac{\bar{V} - U}{u'(c^w)} = \eta S + (1 - \eta)S \\ &= -\tau + \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - \rho) \left(z - \Omega - \frac{1 - n}{n} b \right) \right. \\ &\quad + (1 - p)(1 - \rho^u) \left(\frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right) \\ &\quad + (1 - p) \int_{\epsilon_s^u}^{\epsilon_{stw}} s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\ &\quad + p(1 - \rho^c) \left(\frac{u^c - u(b)}{u'(c^w)} - e^c \right) \\ &\quad \left. + p \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \right] \\ \Leftrightarrow \quad S &= -\tau + \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - \rho) \left(z - \Omega - \frac{1 - n}{n} b \right) \right. \\ &\quad + (1 - p)(1 - \rho^u) \left(\frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right) \\ &\quad + (1 - p) \int_{\epsilon_s^u}^{\epsilon_{stw}} (\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\ &\quad + p(1 - \rho^c) \left(\frac{u^c - u(b)}{u'(c^w)} - e^c \right) \\ &\quad + p \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\ &\quad \left. + (1 - \rho)(\lambda - \eta \cdot f) \cdot \beta \cdot S \right] \end{aligned}$$

Next, we want to replace the tax. To do this, we need to know the budget constraint of the government:

$$\begin{aligned} n^s \cdot \tau &= \frac{n}{1 - \rho} \cdot \left((1 - p) \int_{\epsilon_s^u}^{\epsilon_{stw}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \right. \\ &\quad \left. + p \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \right) \\ &\quad + (1 - n) \cdot b \end{aligned}$$

Inserting the employment equation

$$n = (1 - \rho) \cdot \frac{n^s}{\lambda}$$

gives:

$$\begin{aligned} \tau = & \frac{1}{\lambda} \cdot \left((1 - p) \int_{\epsilon_s^u}^{\infty} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \right. \\ & \left. + p \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \right) \\ & + \frac{(1 - \rho)}{n^s} \cdot b \end{aligned}$$

Inserting the expression for the number of firms that receive a shock

$$n^s = \frac{n}{1 - \rho} \cdot \lambda$$

gives:

$$\begin{aligned} \tau = & \frac{1}{\lambda} \cdot \left((1 - p) \int_{\epsilon_s^u}^{\infty} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \right. \\ & \left. + p \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \right) \\ & + \frac{1}{\lambda} \cdot (1 - \rho) \cdot \left(\frac{1 - n}{n} \cdot b \right) \end{aligned}$$

Inserting the tax into the surplus equation gives:

$$\begin{aligned}
S = & \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - \rho) (z - \Omega) \right. \\
& + (1 - p)(1 - \rho^u) \left(\frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right) \\
& + p(1 - \rho^c) \left(\frac{u^c - u(b)}{u'(c^w)} - e^c \right) \\
& \left. + (1 - \rho)(\lambda - f) \cdot \beta \cdot S \right] \\
& - \left(\frac{1}{\lambda} - \frac{1}{1 - \beta \cdot (1 - \lambda)} \right) \cdot (1 - p) \int_{\epsilon_s^u}^{\epsilon_{stw}} (\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
& - \left(\frac{1}{\lambda} - \frac{1}{1 - \beta \cdot (1 - \lambda)} \right) \cdot p \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
& - \frac{1}{\lambda} \cdot (1 - \rho) \cdot \frac{1 - n}{n} \cdot b
\end{aligned}$$

Inserting the free-entry condition

$$\frac{k_v}{q} = \beta \cdot J$$

gives:

$$\begin{aligned}
\frac{1}{1 - \eta} \cdot \frac{k_v}{q} = & \frac{\beta}{1 - \beta \cdot (1 - \lambda)} \left[(1 - \rho) \left(z - \Omega - \frac{1 - n}{n} \cdot b \right) \right. \\
& + (1 - p)(1 - \rho^u) \left(\frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right) \\
& + p(1 - \rho^c) \left(\frac{u^c - u(b)}{u'(c^w)} - e^c \right) \\
& \left. + (1 - \rho) \cdot \frac{\lambda - \eta \cdot f}{1 - \eta} \cdot \frac{k_v}{q} \right]
\end{aligned}$$

This is the job-creation condition used in the Ramsey problem for STW in Appendix H.

Next, we want to calculate the wage-equation. Remember the surplus splitting rule from Nash-Bargaining:

$$\eta \cdot \bar{J} = (1 - \eta) \cdot \frac{\bar{V} - U}{u'(c^w)}$$

Inserting the tax into the value of a worker for a firm gives:

$$\begin{aligned}\bar{J} = & \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - \rho)(z - \Omega) - p(1 - \rho^u)c^w - (1 - p)(1 - \rho^c)e^c + (1 - \rho)\lambda\beta\bar{J} \right] \\ & - \left(\frac{1}{\lambda} - \frac{1}{1 - \beta \cdot (1 - \lambda)} \right) \cdot (1 - p) \int_{\epsilon_s^u}^{\epsilon_{stw}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\ & - \left(\frac{1}{\lambda} - \frac{1}{1 - \beta \cdot (1 - \lambda)} \right) \cdot p \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\ & - \frac{1}{\lambda} \cdot (1 - \rho) \cdot \frac{1 - n}{n} \cdot b\end{aligned}$$

Likewise, we can calculate the surplus of a worker:

$$\begin{aligned}\bar{V} - U = & \frac{1}{1 - \beta \cdot (1 - \lambda)} \left[(1 - p)(1 - \rho^u)(u(c^w) - u(b)) + p(1 - \rho^c)(u^c - u(b)) \right. \\ & \left. + (1 - \rho)(\lambda - f)\beta(\bar{V} - U) \right]\end{aligned}$$

Next, we can insert the value of a worker for a firm and the surplus of a worker into the surplus splitting rule:

$$\begin{aligned}& \frac{\eta}{1 - \beta \cdot (1 - \lambda)} \cdot \left[(1 - \rho)(z - \Omega) - p(1 - \rho^u) \cdot c^w - (1 - p)(1 - \rho^c) \cdot e^c \right. \\ & \quad \left. + (1 - \rho) \cdot \lambda \cdot \beta \cdot \bar{J} \right] \\ & - \left(\frac{1}{\lambda} - \frac{1}{1 - \beta \cdot (1 - \lambda)} \right) \cdot (1 - p) \int_{\epsilon_s^u}^{\epsilon_{stw}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\ & - \left(\frac{1}{\lambda} - \frac{1}{1 - \beta \cdot (1 - \lambda)} \right) \cdot p \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\ & - \frac{1}{\lambda} \cdot (1 - \rho) \cdot \frac{1 - n}{n} \cdot b \\ & = \frac{1 - \eta}{1 - \beta \cdot (1 - \lambda)} \cdot \frac{1}{u'(c^w)} \cdot \left[(1 - p)(1 - \rho^u) \cdot (u(c^w) - u(b)) \right. \\ & \quad \left. + p(1 - \rho^c) \cdot (u^c - u(b)) \right. \\ & \quad \left. + (1 - \rho)(\lambda - f)\beta(\bar{V} - U) \right]\end{aligned}$$

Insert the surplus splitting rule again: $\eta \cdot \bar{J} = (1 - \eta) \cdot \frac{\bar{V} - U}{u'(c^w)}$

$$\begin{aligned}
& \frac{\eta}{1 - \beta \cdot (1 - \lambda)} \cdot \left[(1 - \rho)(z - \Omega) - p(1 - \rho^u) \cdot c^w - (1 - p)(1 - \rho^c) \cdot e^c \right. \\
& \quad \left. + (1 - \rho) \cdot \lambda \cdot \beta \cdot \bar{J} \right] \\
& \quad - \left(\frac{1}{\lambda} - \frac{1}{1 - \beta \cdot (1 - \lambda)} \right) \cdot (1 - p) \int_{\epsilon_s^u}^{\epsilon_{stw}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
& \quad - \left(\frac{1}{\lambda} - \frac{1}{1 - \beta \cdot (1 - \lambda)} \right) \cdot p \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
& \quad - \frac{1}{\lambda} \cdot (1 - \rho) \cdot \frac{1 - n}{n} \cdot b \\
& = \frac{1 - \eta}{1 - \beta \cdot (1 - \lambda)} \cdot \frac{1}{u'(c^w)} \cdot \left[(1 - p)(1 - \rho^u) \cdot (u(c^w) - u(b)) \right. \\
& \quad \left. + p(1 - \rho^c) \cdot (u^c - u(b)) \right. \\
& \quad \left. + (1 - \rho)(\lambda - f) \cdot u'(c^w) \cdot \frac{\eta}{1 - \eta} \cdot \beta \cdot \bar{J} \right]
\end{aligned}$$

$$\begin{aligned}
\Leftrightarrow & \frac{\eta}{1 - \beta \cdot (1 - \lambda)} \left[(1 - \rho)(z - \Omega) - p(1 - \rho^u) \cdot c^w - (1 - p)(1 - \rho^c) \cdot e^c \right. \\
& \quad \left. + (1 - \rho) \cdot \lambda \cdot f \cdot \beta \cdot \bar{J} \right] \\
& \quad - \left(\frac{1}{\lambda} - \frac{1}{1 - \beta \cdot (1 - \lambda)} \right) \cdot (1 - p) \int_{\epsilon_s^u}^{\epsilon_{stw}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
& \quad - \left(\frac{1}{\lambda} - \frac{1}{1 - \beta \cdot (1 - \lambda)} \right) \cdot p \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
& \quad - \frac{1}{\lambda} \cdot (1 - \rho) \cdot \frac{1 - n}{n} \cdot b \\
& = \frac{1 - \eta}{1 - \beta \cdot (1 - \lambda)} \cdot \frac{1}{u'(c^w)} \left[(1 - p)(1 - \rho^u)(u(c^w) - u(b)) \right. \\
& \quad \left. + p(1 - \rho^c)(u^c - u(b)) \right]
\end{aligned}$$

$$\begin{aligned}
\Leftrightarrow \quad & \eta \cdot \left[(1 - \rho)(z - \Omega) + (1 - \rho) \cdot f \cdot \beta \cdot \bar{J} \right] \\
& - \left(\frac{1 - \beta \cdot (1 - \lambda)}{\lambda} - 1 \right) \cdot (1 - p) \int_{\epsilon_s^u}^{\epsilon_{stw}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
& - \left(\frac{1 - \beta \cdot (1 - \lambda)}{\lambda} - 1 \right) \cdot p \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
& - \frac{1 - \beta \cdot (1 - \lambda)}{\lambda} \cdot (1 - \rho) \cdot \frac{1 - n}{n} \cdot b \\
& = (1 - p)(1 - \rho^u)(1 - \eta) \cdot \left(\frac{u(c^w) - u(b)}{u'(c^w)} + \eta \cdot c^w \right) \\
& + p(1 - \rho^c)(1 - \eta) \cdot \left(\frac{u^c - u(b)}{u'(c^w)} + \eta \cdot e^c \right)
\end{aligned}$$

Inserting the free-entry condition again, we get the wage equation from Appendix H for STW.

$$\begin{aligned}
& (1 - p)(1 - \rho^u)(1 - \eta) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} + \eta \cdot c^w \\
& - \left(\frac{1 - \beta \cdot (1 - \lambda)}{\lambda} - 1 \right) \cdot (1 - p) \int_{\epsilon_s^u}^{\epsilon_{stw}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
& - \left(\frac{1 - \beta \cdot (1 - \lambda)}{\lambda} - 1 \right) \cdot p \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} s_{stw}(\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
& - \frac{1 - \beta \cdot (1 - \lambda)}{\lambda} \cdot (1 - \rho) \cdot \frac{1 - n}{n} \cdot b \\
& = \eta \cdot \left[(1 - \rho)(z - \Omega) - (1 - \rho) \cdot \frac{1 - n}{n} \cdot b + (1 - \rho) \cdot \theta \cdot k_v \right] \\
& - p(1 - \rho^c)(1 - \eta) \cdot \left(\frac{u^c - u(b)}{u'(c^w)} + \eta \cdot e^c \right)
\end{aligned}$$

H The full Ramsey Problems

H.1 Lay-off Tax

For $\beta \rightarrow 1$ the Ramsey planner's problem reads:

$$\begin{aligned}
& \max_{b, s_{stw}, \epsilon_{stw}} n^u \cdot u(c^w) + n^c \cdot u^c + (1 - n) \cdot u(b) \\
& + v^f \cdot u((n \cdot z - n^u \cdot c^w - n^c \cdot e^c - \tau(b) - \theta \cdot (1 - n) \cdot k_v) / v^f)
\end{aligned}$$

subject to the following constraints:

(I) Number of unconstrained workers:

$$n^u = \frac{1 - p}{\lambda} \cdot (1 - \rho^u) \cdot n^s$$

(II) Separation rate, unconstrained workers:

$$\rho^u = G(\epsilon_s^u)$$

(III) Number of constrained workers:

$$n^c = \frac{p}{\lambda} \cdot (1 - \rho^c) \cdot n^s$$

(IV) Separation rate, constrained workers:

$$\rho^c = G(\epsilon_s^c)$$

(V) Aggregate separation rate:

$$\rho = (1 - p) \cdot \rho^u + p \cdot \rho^c$$

(VI) Number of firms that are hit by a shock:

$$n^s = \theta \cdot q(\theta) \cdot (1 - n) + \lambda \cdot n$$

(VII) Total employment:

$$n = n^u + n^c$$

(VIII) Average utility of constrained worker:

$$u^c = \frac{1}{1 - \rho^c} \left((1 - G(\epsilon^p)) \cdot u(c^w) + \int_{\epsilon_s^c}^{\epsilon^p} u(c(\epsilon)) dG(\epsilon) \right)$$

(IX) Average cost of a constrained worker for a firm:

$$e^c = \frac{1}{1 - \rho^c} \left[(1 - G(\epsilon^p)) \cdot c^w + \int_{\epsilon_s^c}^{\epsilon^p} c^w(\epsilon) dG(\epsilon) \right]$$

(X) Average production (without distortions):

$$z = \frac{1}{1 - \rho} \left((1 - p) \int_{\epsilon_s^u}^{\infty} z(\epsilon) dG(\epsilon) + p \int_{\epsilon_s^c}^{\infty} z(\epsilon) dG(\epsilon) \right)$$

(XI) Job-creation condition:

$$\begin{aligned} \frac{1}{1-\eta} \cdot \frac{k_v}{q} = \frac{1}{\lambda} & \left[(1-\rho) \cdot \left(z - \frac{1-n}{n} \cdot b \right) \right. \\ & + (1-p)(1-\rho^u) \cdot \left(\frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right) \\ & + (1-p)(1-\rho^c) \cdot \left(\frac{u^c - u(b)}{u'(c^w)} - e^c \right) \\ & \left. + (1-\rho) \cdot \frac{\lambda - f \cdot \eta}{1-\eta} \cdot \frac{k_v}{q} \right] \end{aligned}$$

(XII) Wage:

$$\begin{aligned} WE = & (1-p) \cdot (1-\rho^u) \cdot \left(\eta \cdot c^w + (1-\eta) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \right) \\ & - \eta \cdot (1-\rho) \cdot \left(z - \frac{1-n}{n} \cdot b + \theta \cdot \frac{k_v}{q} \right) \\ & + p \cdot (1-\rho^c) \cdot \left[(1-\eta) \cdot \frac{u^c - u(b)}{u'(c^w)} + \eta \cdot e^c \right] = 0 \end{aligned}$$

(XIII) Separation condition unconstrained firm:

$$z(\epsilon_s^u) + \lambda \cdot F + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + \frac{\lambda - \eta \cdot f}{1-\eta} \cdot \frac{k_v}{q} = 0$$

(XIV) Threshold at which the constraint is binding:

$$z(\epsilon^p) + \lambda \cdot \frac{k_v}{q} = c^w$$

(XV) Separation condition constrained firm:

$$\frac{u(c^w(\epsilon_s^c)) - u(b)}{u'(c^w)} + (\lambda - f) \cdot \frac{\eta}{1-\eta} \cdot \frac{k_v}{q} = 0$$

(XVI) Consumption of constrained worker:

$$c^w(\epsilon) = z(\epsilon) + \lambda \cdot \frac{k_v}{q}$$

H.2 Short-Time Work

For $\beta \rightarrow 1$ the Ramsey planner's problem reads:

$$\begin{aligned} \max_{b, s_{stw}, \epsilon_{stw}} \quad & n^u \cdot u(c^w) + n^c \cdot u^c + (1 - n) \cdot u(b) \\ & + v^f \cdot u((n \cdot (z - \Omega) - n^u \cdot c^w - n^c \cdot e^c - \tau(b) - \theta \cdot (1 - n) \cdot k_v) / v^f) \end{aligned}$$

subject to the following constraints:

(I) Number of unconstrained workers:

$$n^u = \frac{1 - p}{\lambda} \cdot (1 - \rho^u) \cdot n^s$$

(II) Separation rate (unconstrained workers):

$$\rho^u = G(\epsilon_s^u)$$

(III) Number of constrained workers:

$$n^c = \frac{p}{\lambda} \cdot (1 - \rho^c) \cdot n^s$$

(IV) Separation rate (constrained workers):

$$\rho^c = G(\max\{\xi_s^c, \epsilon_{stw}\}) - G(\max\{\epsilon_{stw}, \epsilon_s^c\}) + G(\xi_s^c)$$

(V) Aggregate separation rate:

$$\rho = (1 - p) \cdot \rho^u + p \cdot \rho^c$$

(VI) Number of firms that are hit by a shock:

$$n^s = \theta \cdot q(\theta) \cdot (1 - n) + \lambda \cdot n$$

(VII) Total employment:

$$n = n^u + n^c$$

(VIII) Average utility of a constrained worker:

$$u^c = \frac{1}{1 - \rho^c} \left((1 - G(\epsilon^p)) \cdot u(c^w) + \int_{\max\{\epsilon_{\text{stw}}, \xi_s^c\}}^{\epsilon^p} u(c^w(\epsilon)) dG(\epsilon) + \int_{\epsilon_s^c}^{\max\{\epsilon_{\text{stw}}, \epsilon_s^c\}} u(c_{\text{stw}}^w(\epsilon)) dG(\epsilon) \right)$$

(IX) Average cost of a constrained worker for a firm:

$$e^c = \frac{1}{1 - \rho^c} \left[(1 - G(\epsilon^p)) \cdot c^w + \int_{\max\{\epsilon_{\text{stw}}, \xi_s^c\}}^{\epsilon^p} c^w(\epsilon) dG(\epsilon) + \int_{\epsilon_s^c}^{\max\{\epsilon_{\text{stw}}, \epsilon_s^c\}} (c_{\text{stw}}^w(\epsilon) - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon))) dG(\epsilon) \right]$$

(X) Average production (without distortions):

$$z = \frac{1}{1 - \rho} \left((1 - p) \int_{\xi_s^u}^{\infty} z(\epsilon) dG(\epsilon) + p \int_{\max\{\xi_s^c, \epsilon_{\text{stw}}\}}^{\infty} z(\epsilon) dG(\epsilon) + p \cdot \int_{\epsilon_s^c}^{\max\{\epsilon_s^c, \epsilon_{\text{stw}}\}} z(\epsilon) dG(\epsilon) \right)$$

(XI) Average distortion of working hours:

$$\Omega = \frac{1}{1 - \rho} \left((1 - p) \int_{\epsilon_s^u}^{\epsilon_{\text{stw}}} \Omega(\epsilon) dG(\epsilon) + p \int_{\epsilon_s^c}^{\max\{\epsilon_{\text{stw}}, \epsilon_s^c\}} \Omega(\epsilon) dG(\epsilon) \right)$$

with $\Omega(\epsilon) = \bar{z}(\epsilon) - z_{\text{stw}}(\epsilon)$

(XII) Job-creation condition:

$$\begin{aligned} \frac{1}{1 - \eta} \cdot \frac{k_v}{q} = \frac{1}{\lambda} & \left[(1 - \rho) \left(z - \Omega - \frac{1 - n}{n} b \right) \right. \\ & + p(1 - \rho^u) \left(\frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right) \\ & + (1 - p)(1 - \rho^c) \left(\frac{u^c - u(b)}{u'(c^w)} - e^c \right) \\ & \left. + (1 - \rho) \cdot \frac{\lambda - \eta \cdot f}{1 - \eta} \cdot \frac{k_v}{q} \right] \end{aligned}$$

(XIII) Wage:

$$\begin{aligned}
WE = & (1-p) \cdot (1-\rho^u) \left(\eta \cdot c^w + (1-\eta) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \right) \\
& - \eta(1-\rho) \left(z - \Omega - \frac{1-n}{n}b + \theta \cdot k_v \right) \\
& + p \cdot (1-\rho^c) \left[(1-\eta) \cdot \frac{u^c - u(b)}{u'(c^w)} + \eta \cdot e^c \right] = 0
\end{aligned}$$

(XIV) Separation condition for unconstrained firm without STW:

$$z(\xi_s^u) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + \frac{\lambda - \eta \cdot f}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

(XV) Separation condition for unconstrained firm with STW:

$$z_{\text{stw}}(\epsilon_s^u) + s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^u)) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + \frac{\lambda - \eta \cdot f}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

(XVI) Threshold at which the constraint is binding:

$$z(\epsilon_p) + \lambda \cdot \frac{k_v}{q} = c^w$$

(XVII) Separation condition, constrained firm without STW:

$$\frac{u(c^w(\xi_s^c)) - u(b)}{u'(c^w)} + (\lambda - f) \cdot \frac{\eta}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

(XVIII) Separation condition, constrained firm with STW:

$$\frac{u(c_{\text{stw}}^w(\epsilon_s^c))}{u'(c^w)} + (\lambda - f) \cdot \frac{\eta}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

(XIX) Consumption, constrained worker outside STW

$$c^w(\epsilon) = z(\epsilon) + \lambda \cdot \frac{k_v}{q}$$

(XX) Consumption, constrained worker on STW

$$c_{\text{stw}}^w(\epsilon) = z_{\text{stw}}(\epsilon) + s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon)) + \lambda \cdot \frac{k_v}{q}$$

I Ramsey FOCs with Lay-Off Tax

In the following, multipliers from the Lagrangian, implied by the maximization problem from the previous section, are denoted by λ_{idx} , the index depending on the constraint. Here, λ_n denotes the Lagrange multiplier for the total employment equation, λ_{n^u} for the number of unconstrained firms, λ_{n^c} for the number of constrained firms, λ_{n^s} for the number of firms that received a shock, λ_θ for the job-creation condition, λ_c for the wage equation, $\lambda_{\epsilon_s^u}$ for the separation condition of unconstrained firms and $\lambda_{\epsilon_s^c}$ for the separation condition of constrained firms. Every other equation listed in the Ramsey problem for the lay-off tax is assumed to be plugged in.

I.1 Employment (Lay-Off Tax)

$$\begin{aligned} \frac{\partial \mathcal{L}}{\partial n^s} &= -\lambda_{n^s} + \frac{1-p}{\lambda} \cdot (1-\rho^u) \cdot (u(c^w) - u'(c^w) \cdot c^u) \\ &\quad + \frac{p}{\lambda} \cdot (1-\rho^c) \cdot (u(c^w) - u'(c^w) \cdot e^c) \\ &\quad + \frac{1-p}{\lambda} \cdot (1-\rho^u) \cdot \lambda_{n^u} + \frac{p}{\lambda} \cdot (1-\rho^c) \cdot \lambda_{n^c} = 0 \end{aligned}$$

$$\frac{\partial \mathcal{L}}{\partial n^u} = -\lambda_{n^u} + \lambda_n = 0$$

$$\frac{\partial \mathcal{L}}{\partial n^c} = -\lambda_{n^c} + \lambda_n = 0$$

$$\begin{aligned} \frac{\partial \mathcal{L}}{\partial n} &= -\lambda_n + \lambda_{n^s} \cdot (\lambda - q(\theta) \cdot \theta) + u'(c^w) \cdot [z + b + \theta \cdot c] - u(b) \\ &\quad + \frac{1-\rho}{\lambda} \cdot \frac{b}{n^2} \cdot \lambda_\theta + \eta(1-\rho) \cdot \frac{b}{n^2} \cdot \lambda_c = 0 \end{aligned}$$

$$\begin{aligned} \Leftrightarrow \quad \frac{\lambda_n}{u'(c^w)} &= (\lambda - q(\theta) \cdot \theta) \cdot \frac{\lambda_{n^s}}{u'(c^w)} + [z + b + \theta \cdot c] - \frac{u(b)}{u'(c^w)} \\ &\quad + \frac{1-\rho}{\lambda} \cdot \frac{b}{n^2} \cdot \frac{\lambda_\theta}{u'(c^w)} + \frac{\lambda \cdot b}{n^2} \cdot \frac{\lambda_c}{u'(c^w)} + \eta \cdot \frac{b}{n^2} \cdot \frac{\lambda_c}{u'(c^w)} \end{aligned}$$

I.2 Optimal Job Creation Condition (Lay-Off Tax)

Before we begin, let us define the insurance effect as:

$$\begin{aligned}\tilde{I}E_\theta &= \frac{p}{\lambda} \left(\int_{\epsilon_s^c}^{\epsilon^p} \lambda \cdot \frac{\gamma}{f} \cdot \frac{u'(c(\epsilon)) - u'(c^w)}{u'(c^w)} dG(\epsilon) \right) \cdot k_v \\ IE_\theta &= n^s \cdot u'(c^w) \cdot \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \tilde{I}E_\theta\end{aligned}$$

The FOC for labor market tightness denotes:

$$\begin{aligned}\frac{\partial \mathcal{L}}{\partial \theta} &= -k_v(1-n)u'(c^w) + IE_\theta \cdot k_v + (1-\gamma)q(\theta)(1-n)\lambda_{n^s} \\ &\quad - \frac{\gamma}{1-\eta}k_v\lambda_\theta + \frac{\lambda\gamma - f\eta}{(1-\eta)f} \left(\frac{1-\rho}{\lambda}\lambda_\theta - \lambda_{\epsilon_s^u} \right) \\ &\quad - \left(\lambda \cdot \frac{\gamma}{f}u'(c(\epsilon_s^u)) + \frac{\lambda\gamma - f}{(1-\eta)f}\eta \right) \lambda_{\epsilon_s^c} \\ &\quad - \lambda_c \cdot \frac{\partial WE}{\partial \theta} \\ \Leftrightarrow \quad \frac{\lambda_{n^s}}{u'(c^w)} &= \frac{1+\chi}{1-\eta} \cdot \frac{k_v}{q}\end{aligned}$$

with

$$\begin{aligned}\chi &= \frac{1}{u \cdot u'(c^w)} \cdot \left[\frac{1}{f} \cdot \frac{1}{1-\eta} \cdot \left(\gamma\lambda_\theta - (\lambda\gamma - f\eta) \left(\frac{1-\rho}{\lambda}\lambda_\theta - \lambda_{\epsilon_s^u} \right) \right) \right. \\ &\quad + \left(\lambda \cdot \frac{\gamma}{f} \cdot u'(c^w(\epsilon_s^u)) + \frac{\lambda\gamma - f}{(1-\eta)f} \cdot \eta \right) \lambda_{\epsilon_s^c} \\ &\quad \left. + \frac{1}{k_v} \cdot \left(\lambda_c \cdot \frac{\partial WE}{\partial \theta} - IE_\theta \right) \right]\end{aligned}$$

Using the FOCs for employment and labor market tightness gives:

$$\begin{aligned}u'(c^w) \cdot \frac{1+\chi}{1-\gamma} \cdot \frac{k_v}{q} &= \frac{1-p}{\lambda} \cdot (1-\rho^u) \cdot (u(c^w) - u(b) - u'(c^w) \cdot c^w) \\ &\quad + \frac{p}{\lambda} \cdot (1-\rho^c) \cdot (u^c - u(b) - u'(c^w) \cdot e^c) \\ &\quad + u'(c^w) \cdot \frac{1-\rho}{\lambda} \cdot \left(z + b + \frac{\lambda - \gamma f + \chi(\lambda - f)}{1-\gamma} \cdot \frac{k_v}{q} \right) \\ &\quad + \frac{1-\rho}{\lambda} \cdot \frac{\lambda_\theta}{n^s} \cdot \frac{b}{n} + \frac{1-\rho}{n^s} \cdot \frac{b}{n} \cdot \lambda_c\end{aligned}$$

Rearranging gives the *Optimal Job Creation Condition*:

$$\begin{aligned} \frac{1+\chi}{1-\gamma} \cdot \frac{k_v}{q} &= \frac{1-\rho}{\lambda} \cdot (z+b) + \frac{1-\rho}{\lambda} \cdot \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \cdot \frac{b}{n} + \frac{1-\rho}{\lambda} \cdot \frac{\lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \cdot \frac{b}{n} \\ &\quad + \frac{1-p}{\lambda} \cdot (1-\rho^u) \cdot \left(\frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right) \\ &\quad + \frac{p}{\lambda} \cdot (1-\rho^c) \cdot \left(\frac{u^c - u(b)}{u'(c^w)} - c^c \right) \\ &\quad + \frac{1-\rho}{\lambda} \cdot \frac{\lambda - \gamma f + \chi \cdot (\lambda - f)}{1-\gamma} \cdot \frac{k_v}{q} \end{aligned}$$

Subtracting the decentralized job-creation condition from the optimal gives:

$$\begin{aligned} \left(\chi - \frac{\eta - \gamma}{1 - \eta} \right) \cdot \frac{1}{1 - \gamma} \cdot \frac{k_v}{q} &= \left(1 + \frac{\lambda_\theta + \eta + \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{1 - \rho}{\lambda} \cdot \frac{b}{n} \\ &\quad + \frac{(1 - \rho) \cdot (\lambda - f)}{\lambda} \cdot \left(\chi - \frac{\eta - \gamma}{1 - \gamma} \right) \cdot \frac{k_v}{q} \end{aligned}$$

Rearranging gives:

$$\begin{aligned} \left(\chi - \frac{\eta - \gamma}{1 - \eta} \right) \cdot \frac{1}{1 - \gamma} \cdot \frac{k_v}{q} &= \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{\frac{1-\rho}{\lambda}}{\rho + (1-\rho) \cdot \frac{f}{\lambda}} \cdot \frac{b}{n} \\ &= \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{b}{f} \end{aligned}$$

I.3 Optimal Separation Condition (Unconstrained Firms)

FOC for the separation threshold of unconstrained firms:

$$\begin{aligned} -\frac{\partial \mathcal{L}}{\partial \epsilon_s^u} &= \frac{n}{1-\rho} \cdot (1-p) \cdot g(\epsilon_s^u) \cdot u'(c^w) \cdot \left(z(\epsilon_s^u) + \frac{u(c^w)}{u'(c^w)} - c^w - z \right) \\ &\quad + \lambda_\theta \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot \left[z(\epsilon_s^u) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w - \frac{1-n}{n} \cdot b + \frac{\lambda - \eta f}{1-\eta} \cdot \frac{k_v}{q} \right] \\ &\quad + \lambda_c \cdot \frac{\partial WE}{\partial \epsilon_s^u} + \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s \cdot \lambda_{n^u} + \lambda_{\epsilon_s^u} \cdot \frac{\partial S_{lt}^u(\epsilon_s^u)}{\partial \epsilon_s^u} = 0 \end{aligned}$$

Insert for λ_{n^u} and subtract decentralized separation condition of unconstrained firms:

$$\begin{aligned} g(\epsilon_s^u) \cdot \frac{1-p}{\lambda} \cdot n^s \cdot \left[z(\epsilon_s^u) + \frac{u(c^w)}{u'(c^w)} - c^w + \frac{\lambda_n}{u'(c^w)} \right] \\ - \frac{\lambda_\theta}{u'(c^w)} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot \left[\lambda F + \frac{1-n}{n} \cdot b \right] \\ + \frac{\lambda_c}{u'(c^w)} \cdot \frac{\partial WE}{\partial \epsilon_s^u} + \frac{\lambda_{\epsilon_s^u}}{u'(c^w)} \cdot \frac{\partial S_{lt}^u(\epsilon_s^u)}{\partial \epsilon_s^u} = 0 \end{aligned}$$

Insert for λ_n :

$$\begin{aligned}
& g(\epsilon_s^u) \cdot \frac{1-p}{\lambda} \cdot n^s \left[z(\epsilon_s^u) + \frac{u(c^w)}{u'(c^w)} - c^w - z \right] \\
& + g(\epsilon_s^u) \cdot \frac{1-p}{\lambda} \cdot n^s \left[(\lambda - q(\theta) \cdot \theta) \cdot \frac{\lambda_{n^s}}{u'(c^w)} + (z + b + \theta \cdot c) - \frac{u(b)}{u'(c^w)} \right. \\
& \quad \left. + \frac{1-\rho}{\lambda} \cdot \frac{b}{n^2} \cdot \frac{\lambda_\theta}{u'(c^w)} + \eta \cdot \frac{b}{n^2} \cdot \frac{\lambda_c}{u'(c^w)} \right] \\
& + \frac{\lambda_\theta}{u'(c^w)} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \left[\lambda F + \frac{1-n}{n} \cdot b \right] \\
& + \frac{\lambda_c}{u'(c^w)} \cdot \frac{\partial W E}{\partial \epsilon_s^u} + \frac{\lambda_{\epsilon_s^u}}{u'(c^w)} \cdot \frac{\partial S_{\text{stw}}^u(\epsilon_s^u)}{\partial \epsilon_s^u} = 0
\end{aligned}$$

$$\begin{aligned}
\Longleftrightarrow & z(\epsilon_s^u) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + b + (\lambda - q(\theta) \cdot \theta) \cdot \frac{\lambda_{n^s}}{u'(c^w)} + \theta \cdot c \\
& - \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \left(\lambda F + \frac{1-n}{n} \cdot b - \frac{b}{n} \right) \\
& + \frac{\lambda_c}{n^s \cdot u'(c^w)} \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial W E}{\partial \epsilon_s^u} \right) \\
& + \frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} \cdot \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial S_{\text{lt}}^u(\epsilon_s^u)}{\partial \epsilon_s^u} = 0
\end{aligned}$$

Inserting λ_n^s gives the *Optimal Separation Condition*:

$$\begin{aligned}
& z(\epsilon_s^u) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + b + \frac{\lambda - \gamma \cdot f + \chi \cdot (\lambda - f)}{1 - \gamma} \cdot \frac{k_v}{q} \\
& - \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \cdot (\lambda \cdot F - b) + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial W E}{\partial \epsilon_s^u} \right) = 0
\end{aligned}$$

Subtracting the decentralized separation condition and rearranging gives:

$$\begin{aligned}
\lambda \cdot F & = b + (\lambda - \theta q(\theta)) \cdot \left(\chi - \frac{\eta - \gamma}{1 - \gamma} \right) \cdot \frac{k_v}{q} \\
& + \frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} \cdot \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial S_{\text{lt}}^u(\epsilon_s^u)}{\partial \epsilon_s^u} \\
& - \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \cdot (\lambda F - b) \\
& + \frac{\lambda_c}{n^s \cdot u'(c^w)} \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial W E}{\partial \epsilon_s^u} \right)
\end{aligned}$$

$$\begin{aligned}
\Longleftrightarrow \quad 0 = & \left(1 + \frac{\lambda_\theta}{u'(c^w) \cdot n^s}\right) \cdot \left(b + (\lambda - f) \cdot \frac{\frac{1-\rho}{\lambda}}{\rho + (1-\rho) \cdot \frac{f}{\lambda}} \cdot \frac{b}{n} - \lambda \cdot F\right) \\
& + \frac{\lambda_c}{n^s \cdot u'(c^w)} \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial WE}{\partial \epsilon_s^u}\right) \\
& + \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} \cdot \frac{\partial S_{\text{lt}}^u(\epsilon_s^u)}{\partial \epsilon_s^u}
\end{aligned}$$

$$\begin{aligned}
\Longleftrightarrow \quad 0 = & \left(1 + \frac{\lambda_\theta}{u'(c^w) \cdot n^s}\right) \cdot \left(b + (\lambda - f) \cdot \frac{b}{f} - \lambda F\right) \\
& + \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} \cdot \frac{\partial S_{\text{stw}}^u(\epsilon_s^u)}{\partial \epsilon_s^u} \\
& + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial WE}{\partial \epsilon_s^u}\right)
\end{aligned}$$

$$\begin{aligned}
\Longleftrightarrow \quad 0 = & \left(1 + \frac{\lambda_\theta}{u'(c^w) \cdot n^s}\right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda F\right) \\
& + \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} \cdot \frac{\partial S_{\text{lt}}^u(\epsilon_s^u)}{\partial \epsilon_s^u} \\
& + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial WE}{\partial \epsilon_s^u}\right)
\end{aligned}$$

Rearranging gives the Lagrange multiplier for unconstrained firms:

$$\begin{aligned}
-\frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} = & \frac{1-p}{\lambda} \cdot \frac{g(\epsilon_s^u)}{\frac{\partial S_{\text{stw}}^u(\epsilon_s^u)}{\partial \epsilon_s^u}} \cdot \left(\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda F\right) \right. \\
& \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial WE}{\partial \epsilon_s^u}\right) \right)
\end{aligned}$$

I.4 Optimal Separation Condition (Constrained Firms)

The FOC for the separation threshold in the constrained firm is:

$$\begin{aligned}
-\frac{\partial \mathcal{L}}{\partial \epsilon_s^c} &= \frac{n}{1-\rho} \cdot p \cdot g(\epsilon_s^c) \cdot u'(c^w) \left(z(\epsilon_s^c) + \frac{u(c^w(\epsilon_s^c)) - u(c^w)}{u'(c^w)} - c^w(\epsilon_s^c) - z \right) \\
&\quad + \lambda_\theta \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \left[z(\epsilon_s^c) + \frac{c^w(\epsilon_s^c) - u(b)}{u'(c^w)} - c^w(\epsilon_s^c) - \frac{1-n}{n} \cdot b + \frac{\lambda - \eta f}{1-\eta} \cdot \frac{k_v}{q} \right] \\
&\quad + \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot \lambda_{nc} \\
&\quad + \lambda_c \cdot \frac{\partial WE}{\partial \epsilon_s^c} \\
&\quad + \lambda_{\epsilon_s^c} \cdot \frac{\partial S_{lt}^c(\epsilon_s^c)}{\partial \epsilon_s^c} = 0
\end{aligned}$$

Note that we can reformulate the decentralized separation threshold of a worker in a constrained firm as:

$$\begin{aligned}
&\frac{u(c^w(\epsilon_s^c)) - u(b)}{u'(c^w)} + (\lambda - f) \cdot \frac{\eta}{1-\eta} \cdot \frac{k_v}{q} = 0 \\
\iff &\frac{u(c^w(\epsilon_s^c)) - u(b)}{u'(c^w)} + (\lambda - f) \cdot \frac{\eta}{1-\eta} \cdot \frac{k_v}{q} = c^w(\epsilon_s^c) - z(\epsilon_s^c) - \lambda \cdot \frac{k_v}{q} \\
\iff &z(\epsilon_s^c) + \frac{u(c^w(\epsilon_s^c)) - u(b)}{u'(c^w)} - c^w(\epsilon_s^c) + \frac{\lambda - \eta f}{1-\eta} \cdot \frac{k_v}{q} = 0
\end{aligned}$$

This simplifies the equation to:

$$\begin{aligned}
-\frac{\partial \mathcal{L}}{\partial \epsilon_s^c} &= \frac{n}{1-\rho} \cdot p \cdot g(\epsilon_s^c) \cdot \left(z(\epsilon_s^c) + \frac{u(c^w(\epsilon_s^c))}{u'(c^w)} - c^w(\epsilon_s^c) - z \right) \\
&\quad + \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot \frac{\lambda_{nc}}{u'(c^w)} \\
&\quad - \frac{\lambda_\theta}{u'(c^w)} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \frac{1-n}{n} \cdot b \\
&\quad + \frac{\lambda_c}{u'(c^w)} \cdot \frac{\partial WE}{\partial \epsilon_s^c} + \frac{\lambda_{\epsilon_s^c}}{u'(c^w)} \cdot \frac{\partial S^c(\epsilon_s^c)}{\partial \epsilon_s^c} \stackrel{!}{=} 0
\end{aligned}$$

Inserting λ_n^s gives the *Optimal Separation Condition*

$$\begin{aligned}
-\frac{\partial \mathcal{L}}{\partial \epsilon_s^c} &= z(\epsilon_s^c) + \frac{u(c^w(\epsilon_s^c))}{u'(c^w)} - c^w(\epsilon_s^c) + b + \frac{\lambda - \gamma \cdot f + \chi \cdot (\lambda - f)}{1-\gamma} \cdot \frac{k_v}{q} \\
&\quad + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \cdot b \\
&\quad + \frac{\lambda_c}{n^s \cdot u'(c^w)} \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \epsilon_s^c} \right) \\
&\quad + \frac{\lambda}{p} \cdot \frac{1}{n^s \cdot g(\epsilon_s^c)} \cdot \frac{\lambda_{\epsilon_s^c}}{u'(c^w)} \cdot \frac{\partial S_{lt}^c(\epsilon_s^c)}{\partial \epsilon_s^c} = 0
\end{aligned}$$

Subtracting the decentralized separation condition gives:

$$\begin{aligned}
0 = & b + (\lambda - \theta q(\theta)) \cdot \left(\chi - \frac{\eta - \gamma}{1 - \eta} \right) \cdot \frac{1}{1 - \gamma} \cdot \frac{k_v}{q} \\
& + \frac{\lambda \cdot \epsilon_s^c}{n^s \cdot u'(c^w)} \cdot \frac{1}{\rho} \cdot \frac{1}{\lambda} \cdot \frac{\partial S_{lt}^c(\epsilon_s^c)}{\partial \epsilon_s^c} \cdot \frac{1}{g(\epsilon_s^c)} \\
& + \frac{\lambda \cdot \theta}{n^s \cdot u'(c^w)} \cdot b + \frac{\lambda_c}{n^s \cdot u'(c^w)} \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \epsilon_s^c} \right)
\end{aligned}$$

Rearranging gives back the Lagrange multiplier:

$$\begin{aligned}
-\frac{\lambda_{\epsilon_s^c}}{n^s \cdot u'(c^w)} = & \frac{p}{\lambda} \cdot \frac{g(\epsilon_s^c)}{\frac{\partial S_{lt}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \cdot \left(\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \frac{\lambda}{f} \cdot b \right. \\
& \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \epsilon_s^c} \right) \right)
\end{aligned}$$

I.5 The Optimal Lay-Off Tax

We start from

$$\frac{\partial \mathcal{L}}{\partial F} = -\lambda_{\epsilon_s^u} = 0$$

Note that the optimal lay-off tax sets the Lagrange multiplier for the separation condition of unconstrained firms equal to zero. This implies that the lay-off tax implements the optimal separation threshold for unconstrained firms. Then

$$\begin{aligned}
-\frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} = & \frac{p}{\lambda} \cdot \frac{g(\epsilon_s^u)}{\frac{\partial S_{lt}^u(\epsilon_s^u)}{\partial \epsilon_s^u}} \cdot \left(\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F \right) \right. \\
& \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{g(\epsilon_s^u)} \cdot \frac{\lambda}{1 - p} \cdot \frac{\partial WE}{\partial \epsilon_s^u} \right) \right)
\end{aligned}$$

This leads to:

$$\begin{aligned}
F = & \frac{1}{f} \cdot b + BE_{lt} \\
BE_{lt} = & \frac{1}{\lambda} \frac{1}{\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right)} \cdot \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda}{1 - p} \cdot \frac{\partial WE}{\partial \epsilon_s^u} \right)
\end{aligned}$$

From the fact that the optimal lay-off tax sets the Lagrange multiplier of the separation condition for unconstrained firms equal to zero, we can infer that the lay-off tax implements the optimal separation rate in the economy when the number of financial constrained firms is equal to zero $p = 0$.

I.6 Optimal UI given Lay-off Tax

From the FOC of UI, we can derive the optimality condition for unemployment insurance. With an optimal lay-off tax, the Lagrange multiplier for the separation condition of the unconstrained firm is equal to zero.

$$\begin{aligned} (1 - \eta) \cdot (u'(b) - u'(c^w)) &= \lambda_\theta \cdot (1 - \rho) \cdot \left(\frac{1 - n}{n} + \frac{u'(b)}{u'(c^w)} \right) \\ &\quad + (\lambda_{\epsilon_s^c} + \lambda_{\xi_s^c}) \cdot \left(-\frac{u'(b)}{u'(c^w)} \right) \\ &\quad + \lambda_c \cdot (1 - \rho) \cdot \left(\eta \cdot \frac{1 - n}{n} - (1 - \eta) \cdot \frac{u'(b)}{u'(c^w)} \right) \end{aligned}$$

To get better insight, we need to determine the Lagrange multipliers for λ_θ , λ_c . We already know the Lagrange multipliers for the separation conditions of constrained firms:

$$\begin{aligned} -\frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} &= \frac{1 - p}{\lambda} \cdot g(\epsilon_s^u) \cdot \frac{1}{\frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial \epsilon_s^u}} \cdot \left[\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F \right) \right. \\ &\quad \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda}{1 - p} \cdot \frac{\partial WE}{\partial \epsilon_s^u} \right) \right] \\ -\frac{\lambda_{\epsilon_s^c}}{n^s \cdot u'(c^w)} &= \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \frac{1}{\frac{\partial S_{stw}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \cdot \left[\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \frac{\lambda}{f} \cdot b \right. \\ &\quad \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \epsilon_s^c} \right) \right] \end{aligned}$$

First, let us find an expression for λ_c :

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial c^w} = & - \left((1-p) \cdot (1-\rho^u) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right. \\
& + p \cdot (1-\rho^c) \cdot \frac{u^c - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \left. \right) \cdot \lambda_\theta \\
& - (1-\eta) \cdot \left((1-p) \cdot (1-\rho^u) \cdot \left(1 - (1-\eta) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right) \right. \\
& \left. - p \cdot (1-\rho^c) \cdot (1-\eta) \cdot \frac{u^c - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right) \cdot \lambda_c \\
& + \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \cdot \lambda_{\epsilon_s^u} \\
& + \frac{u(c_{\text{stw}}(\epsilon_s^c)) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \cdot \lambda_{\epsilon_s^c} = 0
\end{aligned}$$

Next we can solve for the Lagrange multiplier of the wage equation:

$$\begin{aligned}
\lambda_c = & - \frac{1}{\left(\frac{\partial WE}{\partial c^w} \right)^{\text{total}}} \left[\frac{\partial \epsilon_s^u}{\partial c^w} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s \cdot u'(c^w) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F \right) \right. \\
& + \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot u'(c^w) \cdot \frac{\lambda}{f} \cdot b \\
& \left. + \left(- \frac{\partial S^{\text{total}}}{\partial c^w} \right) \cdot \lambda_\theta \right]
\end{aligned}$$

Insert λ_c into the Lagrange multipliers for the separation conditions. To do that, let us rewrite the Lagrange multipliers of the separation conditions:

$$\begin{aligned}
\lambda_{\epsilon_s^u} = & - \frac{1}{\frac{\partial S_{\text{stw}}^u(\epsilon_s^u)}{\partial \epsilon_s^u}} \cdot \left(n^s \cdot u'(c^w) \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F \right) \right. \\
& \left. + \lambda_c \cdot \left(\left(- \frac{\partial n^u}{\partial \epsilon_s^u} \right) \cdot \left(- \frac{\partial WE}{\partial n} \right) + \frac{\partial WE}{\partial \epsilon_s^u} \right) \right) \\
\lambda_{\epsilon_s^c} = & - \frac{1}{\frac{\partial S_{\text{stw}}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \cdot \left(n^s \cdot u'(c^w) \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \frac{\lambda}{f} \cdot b \right. \\
& \left. + \lambda_c \cdot \left(\left(- \frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot \left(- \frac{\partial WE}{\partial n} \right) + \frac{\partial WE}{\partial \epsilon_s^c} \right) \right)
\end{aligned}$$

Inserting λ_c gives:

$$\begin{aligned} \lambda_{\epsilon_s^u} = & -\frac{1}{\frac{\partial S_{\text{stw}}^u(\epsilon_s^u)}{\partial \epsilon_s^u}} \cdot \left(n^s \cdot u'(c^w) \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F \right) \right. \\ & + \left(\left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) \cdot \left(-\frac{\partial c^w}{\partial n} \right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^u} \right)^{\text{total}} \right) \\ & \cdot \left[\frac{\partial \epsilon_s^u}{\partial c^w} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s \cdot u'(c^w) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F \right) \right. \\ & \left. \left. + \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot u'(c^w) \cdot \frac{\lambda}{f} \cdot b + \left(-\frac{\partial S^{\text{total}}}{\partial c^w} \right) \cdot \lambda_\theta \right] \right) \end{aligned}$$

$$\begin{aligned} \lambda_{\epsilon_s^c} = & \frac{1}{\frac{\partial S_{\text{stw}}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \cdot \left(n^s \cdot u'(c^w) \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \frac{\lambda}{f} \cdot b \right. \\ & + \left(\left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot \left(-\frac{\partial c^w}{\partial n} \right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^c} \right)^{\text{total}} \right) \\ & \cdot \left[\frac{\partial \epsilon_s^u}{\partial c^w} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s \cdot u'(c^w) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F \right) \right. \\ & \left. \left. + \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot u'(c^w) \cdot \frac{\lambda}{f} \cdot b + \left(-\frac{\partial S^{\text{total}}}{\partial c^w} \right) \cdot \lambda_\theta \right] \right) \end{aligned}$$

Insert λ_c into the Lagrange multipliers for the separation conditions. To do that, let us rewrite the Lagrange multipliers of the separation conditions:

$$\begin{aligned} \lambda_{\epsilon_s^u} = & -\frac{1}{\frac{\partial S_{\text{stw}}^u(\epsilon_s^u)}{\partial \epsilon_s^u}} \cdot \left(-n^s \cdot u'(c^w) \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \right. \\ & \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F \right) + \lambda_c \cdot \left(\left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) \cdot \left(-\frac{\partial W E}{\partial n} \right) + \frac{\partial W E}{\partial \epsilon_s^u} \right) \Bigg) \\ \lambda_{\epsilon_s^c} = & -\frac{1}{\frac{\partial S_{\text{stw}}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \cdot \left(n^s \cdot u'(c^w) \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \frac{\lambda}{f} \cdot b \right. \\ & \left. + \lambda_c \cdot \left(\left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot \left(-\frac{\partial W E}{\partial n} \right) + \frac{\partial W E}{\partial \epsilon_s^c} \right) \right) \end{aligned}$$

Inserting λ_c gives:

$$\begin{aligned} \lambda_{\epsilon_s^u} = & -\frac{1}{\frac{\partial S_{\text{st}w}^u(\epsilon_s^u)}{\partial \epsilon_s^u}} \cdot \left(n^s \cdot u'(c^w) \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^u) \cdot \left(\lambda + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F \right) \right. \\ & + \left(\left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) \cdot \left(-\frac{\partial c^w}{\partial n} \right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^u} \right)^{\text{total}} \right) \\ & \cdot \left[\frac{\partial \epsilon_s^u}{\partial c^w} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s \cdot u'(c^w) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F \right) \right. \\ & \left. \left. + \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot u'(c^w) \cdot \frac{\lambda}{f} \cdot b + \left(-\frac{\partial S^{\text{total}}}{\partial c^w} \right) \cdot \lambda_\theta \right] \right) \end{aligned}$$

$$\begin{aligned} \lambda_{\epsilon_s^c} = & -\frac{1}{\frac{\partial S_{\text{st}w}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \cdot \left(n^s \cdot u'(c^w) \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \frac{\lambda}{f} \cdot b \right. \\ & + \left(\left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot \left(-\frac{\partial c^w}{\partial n} \right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^c} \right)^{\text{total}} \right) \\ & \cdot \left[\frac{\partial \epsilon_s^u}{\partial c^w} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s \cdot u'(c^w) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F \right) \right. \\ & \left. \left. + \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot u'(c^w) \cdot \frac{\lambda}{f} \cdot b + \left(-\frac{\partial S^{\text{total}}}{\partial c^w} \right) \cdot \lambda_\theta \right] \right) \end{aligned}$$

Now we have everything to calculate λ_θ from the two equations:

$$(1) \quad \left(\chi - \frac{\eta - \gamma}{1 - \eta} \right) \cdot \frac{1}{1 - \gamma} \cdot \frac{k_v}{q} = \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{b}{f}$$

$$\begin{aligned} (2) \quad \chi = & \frac{1}{1 - \eta} \cdot \frac{1}{u \cdot f} \cdot \frac{1}{u'(c^w)} \cdot \left[\gamma - (\lambda\gamma - f\eta) \cdot \left(\frac{1}{\lambda} (1 - \rho) \lambda_\theta - \lambda_{\epsilon_s^u} \right) \right] \\ & + \frac{1}{u} \cdot \frac{1}{u'(c^w)} \cdot \left(\lambda \cdot \frac{\gamma}{f} \cdot u'(c^w) + \left(\frac{1}{1 - \eta} \cdot \frac{\lambda\gamma - f}{f} \right) \cdot \eta \right) \cdot \lambda_{\epsilon_s^c} \\ & + \frac{1}{u} \cdot \frac{1}{u'(c^w)} \cdot \lambda_c \cdot \frac{\partial WE}{\partial \theta} \cdot \frac{1}{k_v} \\ & - \frac{1}{u} \cdot \frac{1}{u'(c^w)} \cdot IE_\theta \end{aligned}$$

We can rearrange (1) to:

$$\chi \cdot k_v = (1 - \gamma) \cdot q \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{b}{f} \right)$$

Note that

$$(1 - \gamma) \cdot q = \frac{\partial f}{\partial \theta}$$

This follows from the fact that:

$$f'(\theta) = q(\theta) + \theta \cdot q'(\theta) = q(\theta) \cdot \left(1 + \frac{q'(\theta) \cdot \theta}{q(\theta)}\right) = q(\theta) \cdot (1 - \gamma)$$

So we can write:

$$\chi \cdot k_v = \left(\frac{\partial f}{\partial \theta}\right) \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)}\right) \cdot \frac{b}{f}\right)$$

Inserting χ gives:

$$\begin{aligned} & \left[\gamma - (\lambda\gamma - f\eta) \cdot \frac{1}{\lambda} \cdot (1 - \rho)\right] \cdot \frac{1}{1 - \eta} \cdot \frac{k_v}{f} \cdot \lambda_\theta \\ &= u'(c^w) \cdot \left(\frac{\partial f}{\partial \theta}\right) \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)}\right) \cdot \frac{b}{f}\right) \\ & \quad + (\lambda\gamma - f\eta) \cdot \frac{1}{1 - \eta} \cdot \frac{k_v}{f} \cdot (-\lambda_{\epsilon_s^u}) \\ & \quad + \left(\lambda \cdot \frac{\gamma}{f} \cdot u'(c^w) + \left(\frac{1}{1 - \eta} \cdot \frac{\lambda\gamma - f}{f}\right) \cdot \eta\right) \cdot k_v \cdot (-\lambda_{\epsilon_s^c}) \\ & \quad + \frac{\partial WE}{\partial \theta} \cdot (-\lambda_c) \quad + IE_\theta \end{aligned}$$

Inserting $\lambda_{\epsilon_s^u}, \lambda_{\epsilon_s^c}, IE_\theta$ gives

$$\begin{aligned} & \left[\gamma - (\lambda\gamma - f\eta) \cdot \frac{1}{\lambda} \cdot (1 - \rho)\right] \cdot \frac{1}{1 - \eta} \cdot \frac{k_v}{f} \cdot \lambda_\theta \\ &= u'(c^w) \cdot \frac{\partial f}{\partial \theta} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)}\right) \cdot \frac{b}{f}\right) \\ & \quad + u'(c^w) \cdot n^s \cdot \left(-\frac{\partial \epsilon_s^u}{\partial \theta}\right)^{\text{total}} \cdot g(\epsilon_s^u) \cdot \frac{1 - p}{\lambda} \cdot \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)}\right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda F\right) \\ & \quad + u'(c^w) \cdot n^s \cdot \left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right)^{\text{total}} \cdot g(\epsilon_s^c) \cdot \frac{p}{\lambda} \cdot \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)}\right) \cdot \frac{\lambda}{f} \cdot b \\ & \quad + \lambda_\theta \cdot \left(-\frac{\partial c^w}{\partial \theta}\right)^{\text{total},2} \cdot \left(-\frac{\partial S}{\partial c^w}\right)^{\text{total}} \\ & \quad + u'(c^w) \cdot n^s \cdot \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)}\right) \cdot \tilde{IE}_\theta \end{aligned}$$

with

$$\begin{aligned}
\left(-\frac{\partial \epsilon_s^u}{\partial \theta}\right)^{\text{total}} &= \left(-\frac{\partial \epsilon_s^u}{\partial \theta}\right) + \left(\frac{\partial c^w}{\partial \theta}\right)^{\text{total}} \cdot \left(-\frac{\partial \epsilon_s^u}{\partial c^w}\right) \\
&\quad + \left(-\frac{\partial \epsilon_s^u}{\partial \theta}\right) \cdot \left[\left(-\frac{\partial n^u}{\partial \epsilon_s^u}\right) \cdot \left(-\frac{\partial c^w}{\partial n}\right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^u}\right)^{\text{total}} \right] \cdot \left(\frac{\partial \epsilon_s^u}{\partial c^w}\right) \\
&\quad + f'(\theta) \cdot \frac{\partial n}{\partial f} \cdot \frac{\partial c^w}{\partial n} \cdot \frac{\partial \epsilon_s^u}{\partial c^w} \\
\left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right)^{\text{total}} &= \left[\left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right) + \left(\frac{\partial c^w}{\partial \theta}\right)^{\text{total}} \cdot \left(-\frac{\partial \epsilon_s^c}{\partial c^w}\right) \right. \\
&\quad + \left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right) \cdot \left[\left(-\frac{\partial n^c}{\partial \epsilon_s^c}\right) \cdot \left(-\frac{\partial c^w}{\partial n}\right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^c}\right)^{\text{total}} \right] \cdot \frac{\partial \epsilon_s^c}{\partial c^w} \\
&\quad \left. + f'(\theta) \cdot \frac{\partial n}{\partial f} \cdot \frac{\partial c^w}{\partial n} \cdot \frac{\partial \epsilon_s^c}{\partial c^w} \right] \\
\left(-\frac{\partial c^w}{\partial \theta}\right)^{\text{total},2} &= \left(-\frac{\partial c^w}{\partial \theta}\right)^{\text{total}} + \left(-\frac{\partial \epsilon_s^u}{\partial \theta}\right) \cdot \left(\left(-\frac{\partial n^u}{\partial \epsilon_s^u}\right) \cdot \left(-\frac{\partial c^w}{\partial n}\right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^u}\right)^{\text{total}} \right) \\
&\quad + \left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right) \cdot \left(\left(-\frac{\partial n^c}{\partial \epsilon_s^c}\right) \cdot \left(-\frac{\partial c^w}{\partial n}\right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^c}\right)^{\text{total}} \right) \\
&\quad + f'(\theta) \cdot \frac{\partial n}{\partial f} \cdot \frac{\partial c^w}{\partial n}
\end{aligned}$$

This allows us to calculate the Lagrange multiplier for the job-creation condition

$$\begin{aligned}
M \cdot \lambda_\theta &= u'(c^w) \cdot \frac{\partial f}{\partial \theta} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \cdot \frac{b}{f} \right) \\
&\quad + u'(c^w) \cdot n^s \cdot \left(-\frac{\partial \epsilon_s^u}{\partial \theta}\right)^{\text{total}} \cdot g(\epsilon_s^u) \cdot \frac{1 - p}{\lambda} \left(\frac{\lambda}{f} b - \lambda F \right) \\
&\quad + u'(c^w) \cdot n^s \cdot \left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right)^{\text{total}} \cdot g(\epsilon_s^c) \cdot \frac{p}{\lambda} \cdot \frac{\lambda}{f} b \\
&\quad + u'(c^w) \cdot n^s \cdot \tilde{I} E_\theta
\end{aligned}$$

with

$$\begin{aligned}
M = & \left[\gamma - (\lambda\gamma - f \cdot \eta) \cdot \frac{1}{\lambda} \cdot (1 - \rho) \right] \cdot \frac{1}{1 - \eta} \cdot \frac{k_v}{f} \\
& + \left(-\frac{\partial f}{\partial \theta} \cdot u \cdot \frac{b}{f} \right) \\
& + \left(\frac{\partial \epsilon_s^u}{\partial \theta} \right)^{\text{total}} \cdot g(\epsilon_s^u) \cdot \frac{1 - p}{\lambda} \cdot \left(\frac{\lambda}{f} b - \lambda \cdot F \right) \\
& + \left(\frac{\partial \epsilon_s^c}{\partial \theta} \right)^{\text{total}} \cdot g(\epsilon_s^c) \cdot \frac{p}{\lambda} \cdot \frac{\lambda}{f} b \\
& + \left(\frac{\partial c^w}{\partial \theta} \right)^{\text{total}} \cdot \left(-\frac{\partial S}{\partial c^w} \right)^{\text{total}} \\
& + \tilde{I}E_\theta
\end{aligned}$$

Note: $\frac{1}{M}$ denotes the general equilibrium effect of an increase of the joint surplus on θ :

$$\left(\frac{\partial \theta}{\partial S} \right)^{\text{ge}} = \frac{1}{M}$$

Further, note that:

$$\begin{aligned}
\frac{\partial n^u}{\partial \epsilon_s^u} &= -g(\epsilon_s^u) \cdot \frac{1 - p}{\lambda} \cdot n^s \\
\frac{\partial n^c}{\partial \epsilon_s^c} &= -g(\epsilon_s^c) \cdot \frac{1 - p}{\lambda} \cdot n^s
\end{aligned}$$

Rearranging for λ_θ gives:

$$\begin{aligned}
\lambda_\theta = & u'(c^w) \cdot \left(\frac{\partial f}{\partial S} \right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \frac{\lambda}{f} \cdot b \right) \\
& + u'(c^w) \cdot \left(-\frac{\partial \epsilon_s^u}{\partial S} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) \cdot \left(\frac{\lambda}{f} b - \lambda F \right) \\
& + u'(c^w) \cdot \left(-\frac{\partial \epsilon_s^c}{\partial S} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot \frac{\lambda}{f} b \\
& + u'(c^w) \cdot n^c \cdot \left(\frac{\partial \theta}{\partial S} \right)^{\text{ge}} \cdot \hat{I}E_\theta
\end{aligned}$$

Note that

$$\begin{aligned}
\left(\frac{\partial f}{\partial S} \right)^{\text{ge}} &= \frac{1}{M} \cdot \frac{\partial f}{\partial S} \\
\left(\frac{\partial \epsilon_s^u}{\partial S} \right)^{\text{ge}} &= \frac{1}{M} \cdot \left(\frac{\partial \epsilon_s^u}{\partial S} \right)^{\text{total}} \\
\left(\frac{\partial \epsilon_s^c}{\partial S} \right)^{\text{ge}} &= \frac{1}{M} \cdot \left(\frac{\partial \epsilon_s^c}{\partial S} \right)^{\text{total}}
\end{aligned}$$

Further define:

$$\hat{I}E_\theta = \frac{1}{1 - \rho^c} \cdot \int_{\epsilon_s^c}^{\epsilon^p} \lambda \cdot \frac{\gamma}{f} \cdot \frac{u'(c_{\text{stw}}(\epsilon)) - u'(c^w)}{u'(c^w)} dG(\epsilon)$$

Finally, we can calculate the Lagrange multiplier for λ_c by inserting into λ_θ :

$$\begin{aligned} \lambda_c = & \frac{-1}{\left(\frac{\partial S}{\partial c^w}\right)^{\text{total}}} \cdot \left[\left(\frac{\partial \epsilon_s^u}{\partial c^w} + \left(\frac{\partial S}{\partial c^w}\right)^{\text{total}} \cdot \left(\frac{\partial \epsilon_s^u}{\partial S}\right)^{\text{ge}} \right) \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s \cdot u'(c^w) \cdot \left(\frac{\lambda}{f} b - \lambda F \right) \right. \\ & + \left(\frac{\partial \epsilon_s^c}{\partial c^w} + \left(\frac{\partial S}{\partial c^w}\right)^{\text{total}} \cdot \left(\frac{\partial \epsilon_s^c}{\partial S}\right)^{\text{ge}} \right) \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot u'(c^w) \cdot \frac{\lambda}{f} b \\ & + \left(\frac{\partial S}{\partial c^w}\right)^{\text{total}} \cdot \left(-\frac{\partial f}{\partial S}\right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1-\gamma)(1-\eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)}\right) \cdot \frac{b}{f} \right) \\ & \left. - n^c \cdot \left(\frac{\partial S}{\partial c^w}\right)^{\text{ge}} \cdot \left(\frac{\partial \theta}{\partial S}\right) \cdot \hat{I}E_\theta \right] \end{aligned}$$

Simplifying:

$$\begin{aligned} \lambda_c = & -\frac{u'(c^w)}{\left(\frac{\partial W E}{\partial c^w}\right)^{\text{total}}} \left[\left(\frac{\partial \epsilon_s^u}{\partial c^w}\right)^{\text{ge}} \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u}\right) \cdot \left(\frac{\lambda}{f} b - \lambda F\right) + \left(\frac{\partial \epsilon_s^c}{\partial c^w}\right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c}\right) \cdot \frac{\lambda}{f} b \right. \\ & \left. + \left(-\frac{\partial f}{\partial c^w}\right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1-\gamma)(1-\eta)} \cdot \frac{k_v}{q} + \frac{b}{f} \right) + n^c \cdot \left(-\frac{\partial \theta}{\partial c^w}\right)^{\text{ge}} \cdot \hat{I}E_\theta \right] \end{aligned}$$

Following the same arguments, we can express the Lagrange multiplier for the separation conditions as:

$$\begin{aligned} \lambda_{\epsilon_s^u} = & -\frac{u'(c^w)}{\left(\frac{\partial S_{\text{stw}}^u(\epsilon_s^u)}{\partial \epsilon_s^u}\right)^{\text{total}}} \left[\left(\left(-\frac{\partial n^u}{\partial \epsilon_s^u}\right) \right)^{\text{ge}} \cdot \left(\frac{\lambda}{f} b - \lambda F\right) + \left(\frac{\partial \epsilon_s^c}{\partial \epsilon_s^u}\right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c}\right) \cdot \frac{\lambda}{f} b \right. \\ & + \frac{\partial c^w}{\partial \epsilon_s^u} \cdot \left(-\frac{\partial f}{\partial c^w}\right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1-\gamma)(1-\eta)} \cdot \frac{k_v}{q} + \frac{b}{f} \right) \\ & \left. + n^c \cdot \frac{\partial c^w}{\partial \epsilon_s^u} \cdot \left(-\frac{\partial \theta}{\partial c^w}\right)^{\text{ge}} \cdot \hat{I}E_\theta \right] \end{aligned}$$

$$\begin{aligned}
\lambda_{\epsilon_s^c} = & -\frac{u'(c^w)}{\left(\frac{\partial S_{\text{st}w}^c(\epsilon_s^c)}{\partial \epsilon_s^c}\right)^{\text{total}}} \left[\frac{\partial \epsilon_s^u}{\partial \epsilon_s^c} \cdot \left(\left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right)^{\text{ge}} \cdot \left(\frac{\lambda}{f} b - \lambda F \right) \right. \right. \\
& + \left(\left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right)^{\text{ge}} \cdot \frac{\lambda}{f} b + \frac{\partial c^w}{\partial \epsilon_s^c} \cdot \left(-\frac{\partial f}{\partial c^w} \right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \frac{b}{f} \right) \right. \\
& \left. \left. + n^c \cdot \frac{\partial c^w}{\partial \epsilon_s^c} \cdot \left(-\frac{\partial \theta}{\partial c^w} \right)^{\text{ge}} \cdot \hat{I} E_\theta \right]
\end{aligned}$$

For convenience, the optimal UI benefits are replicated here:

$$\begin{aligned}
(1 - n) \cdot (u'(b) - u'(c^w)) = & \lambda_\theta \cdot (1 - \rho) \cdot \left(\frac{1 - n}{n} + \frac{u'(b)}{u'(c^w)} \right) \cdot \left(-\frac{u'(b)}{u'(c^w)} \right) \\
& + (\lambda_{\epsilon_s^u} + \lambda_{\epsilon_s^c}) \cdot \left(-\frac{u'(b)}{u'(c^w)} \right) \\
& + \lambda_c \cdot (1 - \rho) \cdot \left(\eta \cdot \frac{1 - n}{n} - (1 - \eta) \cdot \frac{u'(b)}{u'(c^w)} \right)
\end{aligned}$$

Inserting the Lagrange multiplier gives:

$$\begin{aligned}
(1 - n) \cdot (u'(b) - u'(c^w)) & = u'(c^w) \cdot \left[\frac{\partial c^w}{\partial \epsilon_s^u} \cdot \left(-\frac{\partial f}{\partial c^w} \right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \frac{b}{f} \right) \right] \\
& + u'(c^w) \cdot \left[\left(\frac{\partial \epsilon_s^u}{\partial b} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) \cdot \left(\frac{\lambda}{f} b - \lambda F \right) \right] \\
& + u'(c^w) \cdot \left[\left(\frac{\partial \epsilon_s^c}{\partial b} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot \frac{\lambda}{f} b \right] \\
& + u'(c^w) \cdot \left[n^c \cdot \left(-\frac{\partial \theta}{\partial b} \right)^{\text{ge}} \cdot \hat{I} E_\theta \right].
\end{aligned}$$

With:

$$\begin{aligned}
\left(\frac{\partial \epsilon_s^u}{\partial b} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) & = \underbrace{\left(\frac{\partial \epsilon_s^u}{\partial b} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right)}_{\text{direct effects}} \\
& + \underbrace{\left[\frac{\partial S}{\partial b} \cdot \left(\frac{\partial \epsilon_s^u}{\partial S} \right)^{\text{ge}} + \frac{\partial \epsilon_s^c}{\partial b} \cdot \left(\frac{\partial \epsilon_s^u}{\partial \epsilon_s^c} \right)^{\text{ge}} + \frac{\partial c^w}{\partial b} \cdot \left(\frac{\partial \epsilon_s^u}{\partial c^w} \right)^{\text{ge}} \right] \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right)}_{\text{indirect effect}}
\end{aligned}$$

$$\begin{aligned} \left(\frac{\partial \epsilon_s^c}{\partial b}\right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c}\right) &= \underbrace{\left(\frac{\partial \epsilon_s^c}{\partial b}\right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c}\right)}_{\text{direct effects}} \\ &+ \underbrace{\left[\frac{\partial S}{\partial b} \cdot \left(\frac{\partial \epsilon_s^c}{\partial S}\right)^{\text{ge}} + \frac{\partial \epsilon_s^u}{\partial b} \cdot \left(\frac{\partial \epsilon_s^c}{\partial \epsilon_s^u}\right)^{\text{ge}} + \frac{\partial c^w}{\partial b} \cdot \left(\frac{\partial \epsilon_s^c}{\partial c^w}\right)^{\text{ge}}\right] \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c}\right)}_{\text{indirect effect}} \end{aligned}$$

$$\begin{aligned} \left(\frac{\partial f}{\partial b}\right)^{\text{ge}} &= \underbrace{\left(\frac{\partial S}{\partial b} \cdot \left(-\frac{\partial f}{\partial S}\right)^{\text{ge}}\right)}_{\text{direct effect}} \\ &+ \underbrace{\left[\frac{\partial \epsilon_s^u}{\partial b} \cdot \frac{\partial c^w}{\partial \epsilon_s^u} + \frac{\partial \epsilon_s^c}{\partial b} \cdot \frac{\partial c^w}{\partial \epsilon_s^c} + \frac{\partial c^w}{\partial b}\right] \cdot \left(\frac{\partial f}{\partial c^w}\right)^{\text{ge}}}_{\text{indirect effect}} \end{aligned}$$

$$\begin{aligned} \left(\frac{\partial \theta}{\partial b}\right)^{\text{ge}} &= \underbrace{\frac{\partial S}{\partial b} \cdot \left(\frac{\partial \theta}{\partial S}\right)^{\text{ge}}}_{\text{direct effect}} \\ &+ \underbrace{\left[\frac{\partial \epsilon_s^u}{\partial b} \cdot \frac{\partial c^w}{\partial \epsilon_s^u} + \frac{\partial \epsilon_s^c}{\partial b} \cdot \frac{\partial c^w}{\partial \epsilon_s^c} + \frac{\partial c^w}{\partial b}\right] \cdot \left(\frac{\partial \theta}{\partial c^w}\right)^{\text{ge}}}_{\text{indirect effect}} \end{aligned}$$

I.7 Optimal UI under Optimal Lay-off Tax

From the FOC of UI, we can derive the optimality condition for unemployment insurance. In contrast to the section where we take lay-off taxes as given, the government implements the optimal lay-off tax. This implies that the Lagrange multiplier of the separation condition in unconstrained firms is equal to zero. This is also fundamental for the optimality condition for the UI benefits:

$$\begin{aligned} (1 - \eta) \cdot (u'(b) - u'(c^w)) &= \lambda_\theta \cdot (1 - \rho) \cdot \left(\frac{1 - n}{n} + \frac{u'(b)}{u'(c^w)}\right) + \lambda_{\epsilon_s^u} \cdot \left(-\frac{u'(b)}{u'(c^w)}\right) \\ &+ \lambda_c \cdot (1 - \rho) \cdot \left(\eta \cdot \frac{1 - n}{n} + (1 - \eta) \cdot \frac{u'(b)}{u'(c^w)}\right) \end{aligned}$$

The Lagrange multiplier for the separation condition of unconstrained firms is equal to

$$\begin{aligned} -\frac{\lambda_{\epsilon_s^c}}{n^s \cdot u'(c^w)} &= \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \frac{1}{\frac{\partial S_{\text{stw}}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \cdot \left[\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right) \cdot \frac{\lambda}{f} \cdot b \right. \\ &\quad \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial W E}{\partial \epsilon_s^c}\right)\right] \end{aligned}$$

First, let us find an expression for λ_c :

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial c^w} = & - \left((1-p) \cdot (1-\rho^u) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right. \\
& + p \cdot (1-\rho^c) \cdot \frac{u^c - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \left. \right) \cdot \lambda_\theta \\
& - (1-\eta) \cdot \left((1-p) \cdot (1-\rho^u) \cdot \left(1 - (1-\eta) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right) \right. \\
& \left. - p \cdot (1-\rho^c) \cdot (1-\eta) \cdot \frac{u^c - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right) \cdot \lambda_c \\
& + \frac{u(c_{\text{stw}}(\epsilon_s^c)) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \cdot \lambda_{\epsilon_s^c} = 0
\end{aligned}$$

Insert Lagrange multipliers for separation condition:

$$\begin{aligned}
& - \left((1-p) \cdot (1-\rho^u) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right. \\
& \left. + p \cdot (1-\rho^c) \cdot \frac{u^c - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right) \cdot \lambda_\theta \\
& - (1-\eta) \cdot (1-p) \cdot (1-\rho^u) \cdot \left(1 - (1-\eta) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right) \\
& \cdot p \cdot (1-\rho^c) \cdot (1-\eta) \cdot \frac{u^c - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \cdot \lambda_c \\
& + \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \left((n^s \cdot u'(c^w) + \lambda_\theta) \cdot \left(\frac{\lambda}{f} \cdot b \right) \right. \\
& \left. + \lambda_c \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \epsilon_s^c} \right) \right) = 0
\end{aligned}$$

Rearranging gives:

$$\begin{aligned}
0 = & \lambda_\theta \cdot \frac{\partial S^{\text{total}}}{\partial c^w} \\
& + \lambda_c \cdot \frac{\partial WE^{\text{total}}}{\partial c^w} \\
& + \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot u'(c^w) \cdot \frac{\lambda}{f} b
\end{aligned}$$

with

$$\begin{aligned} \frac{\partial S^{\text{total}}}{\partial c^w} = & \left[p(1 - \rho^u) \frac{u(c^w) - u(b)}{u'(c^w)} \frac{u''(c^w)}{u'(c^w)} \right. \\ & - (1 - p)(1 - \rho^c) \frac{u^c - u(b)}{u'(c^w)} \frac{u''(c^w)}{u'(c^w)} \\ & \left. + \frac{\partial \epsilon_s^c}{\partial \theta} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \frac{\lambda}{f} b \right] \end{aligned}$$

and

$$\begin{aligned} \frac{\partial WE^{\text{total}}}{\partial c^w} = & \left[- (1 - \eta)(1 - p\rho^u) \left(1 - (1 - \eta) \frac{u(c^w) - u(b)}{u'(c^w)} \frac{u''(c^w)}{u'(c^w)} \right) \right. \\ & + (1 - (1 - p)\rho^c)(1 - \eta) \frac{u^c - u(b)}{u'(c^w)} \frac{u''(c^w)}{u'(c^w)} \\ & \left. + \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \lambda_c \left(\eta \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \epsilon_s^c} \right) \right] \end{aligned}$$

Next we can solve for the Lagrange multiplier of the wage equation:

$$\begin{aligned} \lambda_c = & - \frac{1}{\left(\frac{\partial WE}{\partial c^w} \right)^{\text{total}}} \left[\frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot u'(c^w) \cdot \frac{\lambda}{f} \cdot b \right. \\ & \left. + \left(- \frac{\partial S^{\text{total}}}{\partial c^w} \right) \cdot \lambda_\theta \right] \end{aligned}$$

Now we have everything to calculate λ_θ from the two equations:

$$(1) \quad \left(\chi - \frac{\eta - \gamma}{1 - \eta} \right) \cdot \frac{1}{1 - \gamma} \cdot \frac{k_v}{q} = \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{b}{f}$$

$$\begin{aligned} (2) \quad \chi = & \frac{1}{1 - \eta} \cdot \frac{1}{u \cdot f} \cdot \frac{1}{u'(c^w)} \cdot \left[\gamma - (\lambda\gamma - f\eta) \cdot \left(\frac{1}{\lambda}(1 - \rho)\lambda_\theta \right) \right] \\ & + \frac{1}{u} \cdot \frac{1}{u'(c^w)} \cdot \left(\lambda \cdot \frac{\gamma}{f} \cdot u'(c^w) + \left(\frac{1}{1 - \eta} \cdot \frac{\lambda\gamma - f}{f} \right) \cdot \eta \right) \cdot \lambda_{\epsilon_s^c} \\ & + \frac{1}{u} \cdot \frac{1}{u'(c^w)} \cdot \lambda_c \cdot \frac{\partial WE}{\partial \theta} \cdot \frac{1}{k_v} \\ & - \frac{1}{u} \cdot \frac{1}{u'(c^w)} \cdot IE_\theta \end{aligned}$$

We can rearrange (1) to:

$$\chi \cdot k_v = (1 - \gamma) \cdot q \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{b}{f} \right)$$

Note that

$$(1 - \gamma) \cdot q = \frac{\partial f}{\partial \theta}$$

This follows from the fact that:

$$f'(\theta) = q(\theta) + \theta \cdot q'(\theta) = q(\theta) \cdot \left(1 + \frac{q'(\theta) \cdot \theta}{q(\theta)} \right) = q(\theta) \cdot (1 - \gamma)$$

So we can write:

$$\chi \cdot k_v = \left(\frac{\partial f}{\partial \theta} \right) \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{b}{f} \right)$$

Inserting χ gives:

$$\begin{aligned} & \left[\gamma - (\lambda\gamma - f\eta) \cdot \frac{1}{\lambda} \cdot (1 - \rho) \right] \cdot \frac{1}{1 - \eta} \cdot \frac{k_v}{f} \cdot \lambda_\theta \\ &= u'(c^w) \cdot \left(\frac{\partial f}{\partial \theta} \right) \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{b}{f} \right) \\ & \quad + \left(\lambda \cdot \frac{\gamma}{f} \cdot u'(c^w) + \left(\frac{1}{1 - \eta} \cdot \frac{\lambda\gamma - f}{f} \right) \cdot \eta \right) \cdot k_v \cdot (-\lambda_{\epsilon_s^c}) \\ & \quad + \frac{\partial WE}{\partial \theta} \cdot (-\lambda_c) \quad + IE_\theta \end{aligned}$$

Inserting $\lambda_{\epsilon_s^c}, IE_\theta$ gives

$$\begin{aligned} & \left[\gamma - (\lambda\gamma - f\eta) \cdot \frac{1}{\lambda} \cdot (1 - \rho) \right] \cdot \frac{1}{1 - \eta} \cdot \frac{k_v}{f} \cdot \lambda_\theta \\ &= u'(c^w) \cdot \frac{\partial f}{\partial \theta} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \cdot \frac{b}{f} \right) \\ & \quad + u'(c^w) \cdot n^s \cdot \left(-\frac{\partial \epsilon_s^c}{\partial \theta} \right)^{\text{total}} \cdot g(\epsilon_s^c) \cdot \frac{p}{\lambda} \cdot \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \cdot \frac{\lambda}{f} \cdot b \\ & \quad + \lambda_\theta \cdot \left(-\frac{\partial c^w}{\partial \theta} \right)^{\text{total}, 2} \cdot \left(-\frac{\partial S}{\partial c^w} \right)^{\text{total}} \\ & \quad + u'(c^w) \cdot n^s \cdot \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \cdot \tilde{IE}_\theta \end{aligned}$$

with

$$\begin{aligned}
\left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right)^{\text{total}} &= \left[\left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right) + \left(\frac{\partial c^w}{\partial \theta}\right)^{\text{total}} \cdot \left(-\frac{\partial \epsilon_s^c}{\partial c^w}\right) \right. \\
&\quad \left. + \left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right) \cdot \left(\left(-\frac{\partial n^c}{\partial \epsilon_s^c}\right) \cdot \left(-\frac{\partial c^w}{\partial n}\right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^c}\right)^{\text{total}} \right) \right] \cdot \frac{\partial \epsilon_s^c}{\partial c^w} \\
&\quad + f'(\theta) \cdot \frac{\partial n}{\partial f} \cdot \frac{\partial c^w}{\partial n} \cdot \frac{\partial \epsilon_s^c}{\partial c^w} \\
\left(-\frac{\partial c^w}{\partial \theta}\right)^{\text{total},2} &= \left(-\frac{\partial c^w}{\partial \theta}\right)^{\text{total}} \\
&\quad + \left(-\frac{\partial \epsilon_s^u}{\partial \theta}\right) \cdot \left(\left(-\frac{\partial n^c}{\partial \epsilon_s^c}\right) \cdot \left(-\frac{\partial c^w}{\partial n}\right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^c}\right)^{\text{total}} \right) \\
&\quad + f'(\theta) \cdot \frac{\partial n}{\partial f} \cdot \frac{\partial c^w}{\partial n}
\end{aligned}$$

This allows us to calculate the Lagrange multiplier for the job-creation condition

$$\begin{aligned}
M \cdot \lambda_\theta &= u'(c^w) \cdot \frac{\partial f}{\partial \theta} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \cdot \frac{b}{f} \right) \\
&\quad + u'(c^w) \cdot n^s \cdot \left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right)^{\text{total}} \cdot g(\epsilon_s^c) \cdot \frac{p}{\lambda} \cdot \frac{\lambda}{f} b \\
&\quad + u'(c^w) \cdot n^s \cdot \tilde{I} E_\theta
\end{aligned}$$

with

$$\begin{aligned}
M &= \left[\gamma - (\lambda \gamma - f \cdot \eta) \cdot \frac{1}{\lambda} \cdot (1 - \rho) \right] \cdot \frac{1}{1 - \eta} \cdot \frac{k_v}{f} \\
&\quad + \left(-\frac{\partial f}{\partial \theta} \cdot u \cdot \frac{b}{f} \right) \\
&\quad + \left(\frac{\partial \epsilon_s^c}{\partial \theta} \right)^{\text{total}} \cdot g(\epsilon_s^c) \cdot \frac{p}{\lambda} \cdot \frac{\lambda}{f} b \\
&\quad + \left(\frac{\partial c^w}{\partial \theta} \right)^{\text{total}} \cdot \left(-\frac{\partial S}{\partial c^w} \right)^{\text{total}} \\
&\quad + \tilde{I} E_\theta
\end{aligned}$$

Note: $\frac{1}{M}$ denotes the general equilibrium effect of an increase of the joint surplus on θ :

$$\left(\frac{\partial \theta}{\partial S} \right)^{\text{ge}} = \frac{1}{M}$$

Rearranging for λ_θ gives:

$$\begin{aligned}\lambda_\theta &= u'(c^w) \cdot \left(\frac{\partial f}{\partial S} \right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \frac{\lambda}{f} \cdot b \right) \\ &\quad + u'(c^w) \cdot \left(-\frac{\partial \epsilon_s^c}{\partial S} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot \frac{\lambda}{f} b \\ &\quad + u'(c^w) \cdot n^c \cdot \left(\frac{\partial \theta}{\partial S} \right)^{\text{ge}} \cdot \hat{I}E_\theta\end{aligned}$$

Note that

$$\begin{aligned}\left(\frac{\partial f}{\partial S} \right)^{\text{ge}} &= \frac{1}{M} \cdot \frac{\partial f}{\partial S} \\ \left(\frac{\partial \epsilon_s^c}{\partial S} \right)^{\text{ge}} &= \frac{1}{M} \cdot \left(\frac{\partial \epsilon_s^c}{\partial S} \right)^{\text{total}}\end{aligned}$$

Further define:

$$\hat{I}E_\theta = \frac{1}{1 - \rho^c} \cdot \int_{\epsilon_s^c}^{\epsilon^p} \lambda \cdot \frac{\gamma}{f} \cdot \frac{u'(c_{\text{stw}}(\epsilon)) - u'(c^w)}{u'(c^w)} dG(\epsilon)$$

Finally, we can calculate the Lagrange multiplier for λ_c by inserting into λ_θ :

$$\begin{aligned}\lambda_c &= \frac{-1}{\left(\frac{\partial S}{\partial c^w} \right)^{\text{total}}} \left[\left(\frac{\partial \epsilon_s^c}{\partial c^w} + \left(\frac{\partial S}{\partial c^w} \right)^{\text{total}} \cdot \left(\frac{\partial \epsilon_s^c}{\partial S} \right)^{\text{ge}} \right) \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot u'(c^w) \cdot \frac{\lambda}{f} b \right. \\ &\quad + \left(\frac{\partial S}{\partial c^w} \right)^{\text{total}} \cdot \left(-\frac{\partial f}{\partial S} \right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \cdot \frac{b}{f} \right) \\ &\quad \left. + n^c \cdot \left(\frac{\partial S}{\partial c^w} \right)^{\text{ge}} \cdot \left(-\frac{\partial \theta}{\partial c^w} \right) \cdot \hat{I}E_\theta \right]\end{aligned}$$

Simplifying:

$$\begin{aligned}\lambda_c &= -\frac{u'(c^w)}{\left(\frac{\partial W E}{\partial c^w} \right)^{\text{total}}} \left[\left(\frac{\partial \epsilon_s^u}{\partial c^w} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) \cdot \left(\frac{\lambda}{f} b - \lambda F \right) + \left(\frac{\partial \epsilon_s^c}{\partial c^w} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot \frac{\lambda}{f} b \right. \\ &\quad \left. + \left(-\frac{\partial f}{\partial c^w} \right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \frac{b}{f} \right) + n^c \cdot \left(-\frac{\partial \theta}{\partial c^w} \right)^{\text{ge}} \cdot \hat{I}E_\theta \right]\end{aligned}$$

Following the same arguments, we can express the Lagrange multiplier for the separation

condition as:

$$\lambda_{\epsilon_s^c} = -\frac{u'(c^w)}{\left(\frac{\partial S_{\text{stw}}^c(\epsilon_s^c)}{\partial \epsilon_s^c}\right)^{\text{total}}} \left[\frac{\partial \epsilon_s^u}{\partial \epsilon_s^c} \cdot \left(\left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) \right)^{\text{ge}} \cdot \left(\frac{\lambda}{f} b - \lambda F \right) + \left(\left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \right)^{\text{ge}} \cdot \frac{\lambda}{f} b \right. \\ \left. + \frac{\partial c^w}{\partial \epsilon_s^c} \cdot \left(-\frac{\partial f}{\partial c^w} \right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \frac{b}{f} \right) + \frac{\partial c^w}{\partial \epsilon_s^c} \cdot \left(-\frac{\partial \theta}{\partial c^w} \right)^{\text{ge}} \cdot \hat{I}E_\theta \right]$$

For convenience, the optimal UI benefits are replicated here:

$$(1 - n) \cdot (u'(b) - u'(c^w)) = \lambda_\theta \cdot (1 - \rho) \cdot \left(\frac{1 - n}{n} + \frac{u'(b)}{u'(c^w)} \right) \cdot \left(-\frac{u'(b)}{u'(c^w)} \right) \\ + \lambda_{\epsilon_s^c} \cdot \left(-\frac{u'(b)}{u'(c^w)} \right) \\ + \lambda_c \cdot (1 - \rho) \cdot \left(\eta \cdot \frac{1 - n}{n} + (1 - \eta) \cdot \frac{u'(b)}{u'(c^w)} \right)$$

Inserting the Lagrange multiplier gives

$$(1 - n) \cdot (u'(b) - u'(c^w)) = u'(c^w) \cdot \left[\left(-\frac{\partial f}{\partial b} \right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \frac{b}{f} \right) \right. \\ \left. + \left(\frac{\partial \epsilon_s^c}{\partial b} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot \frac{\lambda}{f} b \right. \\ \left. + n^c \cdot \left(-\frac{\partial \theta}{\partial b} \right)^{\text{ge}} \cdot \hat{I}E_\theta \right]$$

with

$$\left(\frac{\partial \epsilon_s^c}{\partial b} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) = \underbrace{\left(\frac{\partial \epsilon_s^c}{\partial b} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right)}_{\text{direct effects}} + \underbrace{\left[\frac{\partial S}{\partial b} \cdot \left(\frac{\partial \epsilon_s^c}{\partial S} \right)^{\text{ge}} + \frac{\partial c^w}{\partial b} \cdot \left(\frac{\partial \epsilon_s^c}{\partial c^w} \right)^{\text{ge}} \right] \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right)}_{\text{indirect effect}} \\ \left(\frac{\partial f}{\partial b} \right)^{\text{ge}} = \underbrace{\left(\frac{\partial S}{\partial b} \cdot \left(-\frac{\partial f}{\partial S} \right)^{\text{ge}} \right)}_{\text{direct effect}} + \underbrace{\left[\frac{\partial \epsilon_s^c}{\partial b} \cdot \frac{\partial c^w}{\partial \epsilon_s^c} + \frac{\partial c^w}{\partial b} \right] \cdot \left(\frac{\partial f}{\partial c^w} \right)^{\text{ge}}}_{\text{indirect effect}} \\ \left(\frac{\partial \theta}{\partial b} \right)^{\text{ge}} = \underbrace{\frac{\partial S}{\partial b} \cdot \left(\frac{\partial \theta}{\partial S} \right)^{\text{ge}}}_{\text{direct effect}} + \underbrace{\left[\frac{\partial \epsilon_s^c}{\partial b} \cdot \frac{\partial c^w}{\partial \epsilon_s^c} + \frac{\partial c^w}{\partial b} \right] \cdot \left(\frac{\partial \theta}{\partial c^w} \right)^{\text{ge}}}_{\text{indirect effect}}$$

Inserting the Lagrange multiplier gives

$$(1 - n) \cdot \frac{(u'(b) - u'(c^w))}{u'(c^w)} = \left(-\frac{\partial f}{\partial b} \right)^{\text{ge}} \cdot u \cdot L_v \\ + \left(\frac{\partial \epsilon_s^c}{\partial b} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot L_s^c + n^c \cdot \left(-\frac{\partial \theta}{\partial b} \right)^{\text{ge}} \cdot \hat{I}E_\theta$$

Note that when we set the lay-off tax optimally, then UI will not impose any distortions on the separation condition of unconstrained firms. In the context of Proposition 1, this means that $MLS^u = 0$, bolstering the fact that optimal lay-off taxes can implement the optimal number of separations.

J Ramsey FOCs with STW

In the following, multipliers from the Lagrangian, implied by the maximization problem from the previous section, are denoted by λ_{idx} , the index depending on the constraint. Here, λ_n denotes the Lagrange multiplier for the total employment equation, λ_{n^u} for the number of unconstrained firms, λ_{n^c} for the number of constrained firms, λ_{n^s} for the number of firms that received a shock, λ_θ for the job-creation condition, λ_c for the wage equation, $\lambda_{\epsilon_s^u}$ for the separation condition of unconstrained firms with STW support, $\lambda_{\xi_s^c}$ for the separation condition of constrained firms without STW support, and $\lambda_{\epsilon_s^c}$ for the separation condition of constrained firms with STW support. Every other equation listed in the Ramsey problem for STW is assumed to be plugged in.

J.1 Employment

$$\begin{aligned}\frac{\partial \mathcal{L}}{\partial n^s} &= -\lambda_{n^s} + \frac{1-p}{\lambda} (1-\rho^u) \cdot (u(c^w) - u'(c^w) \cdot c^w) \\ &\quad + \frac{p}{\lambda} (1-\rho^c) \cdot (u^c - u'(c^w) \cdot e^c) \\ &\quad + \frac{1-p}{\lambda} \cdot (1-\rho^c) \cdot \lambda_{n^u} + \frac{p}{\lambda} (1-\rho^c) \cdot \lambda_{n^c} = 0\end{aligned}$$

$$\frac{\partial \mathcal{L}}{\partial n^u} = -\lambda_{n^u} + \lambda_n = 0$$

$$\frac{\partial \mathcal{L}}{\partial n^c} = -\lambda_{n^c} + \lambda_n = 0$$

$$\begin{aligned}\frac{\partial \mathcal{L}}{\partial n} &= -\lambda_n + \lambda_{n^s} \cdot (\lambda - q(\theta) \cdot \theta) \\ &\quad + u'(c^w) \cdot [(z - \Omega) + b + \theta \cdot k_v] - u(b) \\ &\quad + \frac{(1-\rho)}{\lambda} \cdot \frac{b}{n^2} \cdot \lambda_\theta + \eta(1-\rho) \cdot \frac{b}{n^2} \cdot \lambda_c\end{aligned}$$

$$\begin{aligned}\Leftrightarrow \quad \frac{\lambda_n}{u'(c^w)} &= (\lambda - q(\theta) \cdot \theta) + [z - \Omega + b + \theta \cdot k_v] - \frac{u(b)}{u'(c^w)} \\ &\quad + \frac{1-\rho}{\lambda} \cdot \frac{b}{n^2} \cdot \frac{\lambda_\theta}{u'(c^w)} + \eta \cdot (1-\rho) \cdot \frac{b}{n^2} \cdot \frac{\lambda_c}{u'(c^w)}\end{aligned}$$

J.2 Job Creation

Before we start, let us define the Insurance effect:

$$IE_\theta = n^s \cdot u'(c^w) \cdot \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right) \cdot \tilde{IE}_\theta$$

$$\begin{aligned}\tilde{IE}_\theta &= \frac{p}{\lambda} \left(\int_{\max\{\xi_s^c, \epsilon_{stw}\}}^{\epsilon_p} \frac{\lambda}{f} \cdot \gamma \cdot \frac{u'(c(\epsilon)) - u'(c^w)}{u'(c^w)} dG(\epsilon) \right. \\ &\quad \left. + \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} \frac{\lambda}{f} \cdot \gamma \cdot \frac{u'(c_{stw}(\epsilon)) - u'(c^w)}{u'(c^w)} dG(\epsilon) \right) \cdot k_v\end{aligned}$$

The FOC for the labor market tightness can be written as:

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial \theta} &= -k_v(1-n) \cdot u'(c^w) + IE_\theta + (1-\gamma) \cdot q(\theta) \cdot (1-n) \cdot \lambda_{n^s} \\
&\quad - \frac{1}{1-\eta} \cdot \gamma \cdot k_v + \frac{\lambda_\theta}{f} + \frac{1}{1-\eta} \cdot \frac{\lambda\gamma - f\eta}{f} \cdot \left(\frac{1}{\lambda} \cdot (1-\rho) \cdot \lambda_\theta - \lambda_{\epsilon_s^u} \right) \\
&\quad - \left(\lambda \cdot \frac{\gamma}{f} \cdot u'(c_{\text{stw}}^w(\epsilon_s^c)) + \left(\frac{1}{1-\eta} \cdot \frac{\lambda\gamma - f}{f} \right) \eta \right) \cdot \lambda_{\epsilon_s^c} \\
&\quad - \left(\lambda \cdot \frac{\gamma}{f} \cdot u'(c^w(\xi_s^c)) + \frac{1}{\lambda} \cdot \left(\frac{1}{1-\eta} \cdot \frac{\lambda\gamma - f}{f} \right) \eta \right) \cdot \lambda_{\xi_s^c} \\
&\quad - \lambda_c \cdot \frac{\partial WE}{\partial \theta} \\
&\iff \frac{\lambda_{n^s}}{u'(c^w)} = \frac{1+\chi}{1-\gamma} \cdot \frac{k_v}{q}
\end{aligned}$$

$$\begin{aligned}
\text{with } \chi &= \frac{1}{(1-n) \cdot u'(c^w)} \cdot \frac{1}{f} \\
&\cdot \frac{1}{1-\eta} \cdot \left(\gamma \cdot \lambda_\theta - (\lambda \cdot \gamma - f \cdot \eta) \cdot \left(\frac{1}{\lambda} \cdot (1-\rho) \cdot \lambda_\theta - \lambda_{\epsilon_s^u} \right) \right) \\
&\quad + \frac{1}{(1-n) \cdot u'(c^w)} \left(\lambda \cdot \frac{\gamma}{f} u'(c_{\text{stw}}^w(\epsilon_s^c)) + \left(\frac{1}{1-\eta} \cdot \frac{\lambda\gamma - f}{f} \right) \eta \right) \cdot \lambda_{\epsilon_s^c} \\
&\quad + \frac{1}{(1-n) \cdot u'(c^w)} \left(\lambda \cdot \frac{\gamma}{f} u'(c^w(\xi_s^c)) + \left(\frac{1}{1-\eta} \cdot \frac{\lambda\gamma - f}{f} \right) \eta \right) \cdot \lambda_{\xi_s^c} \\
&\quad + \frac{\lambda_c}{(1-n) \cdot u'(c^w)} \cdot \frac{\partial WE}{\partial \theta} / k_v \\
&\quad - \frac{1}{(1-n) \cdot u'(c^w)} \cdot IE_\theta / k_v
\end{aligned}$$

Collecting terms from FOCs for employment and job-creation conditions gives:

$$\begin{aligned}
u'(c^w) \cdot \frac{1+\chi}{1-\gamma} \cdot \frac{k_v}{q} &= \frac{1-p}{\lambda} \cdot (1-\rho^u) \cdot (u(c^w) - u(b) - u'(c^w) \cdot c^w) \\
&\quad + \frac{p}{\lambda} \cdot (1-\rho^c) \cdot (u^c - u(b) - u'(c^w) \cdot e^c) \\
&\quad + \left(\frac{1-\rho}{\lambda} \cdot \frac{b}{n} \cdot \frac{\lambda_\theta}{n^s} \right) + \left(\frac{1-\rho}{\lambda} \cdot \frac{\lambda_c}{n^s} \cdot \eta \cdot \lambda_c \cdot \frac{b}{n} \right) \\
&\quad + u'(c^w) \cdot \frac{1-\rho}{\lambda} \cdot \left(z - \Omega + b + \frac{\lambda - \gamma f + \chi(1-f)}{1-\gamma} \cdot \frac{k_v}{q} \right)
\end{aligned}$$

Optimal Job Creation Condition:

$$\begin{aligned}
\frac{1+\chi}{1-\gamma} \cdot \frac{k_v}{q} &= \frac{1-\rho}{\lambda} \cdot (z - \Omega + b) \\
&+ \frac{1-\rho}{\lambda} \cdot \frac{b}{n} \cdot \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \\
&+ \frac{1-\rho}{\lambda} \cdot \frac{b}{n} \cdot \frac{\lambda_c \cdot \lambda}{n^s \cdot u'(c^w)} \\
&+ \frac{1-p}{\lambda} \cdot (1-\rho^u) \cdot \left(\frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right) \\
&+ \frac{p}{\lambda} \cdot (1-\rho^c) \cdot \left(\frac{u^c - u(b)}{u'(c^w)} - e^c \right) \\
&+ \frac{1-\rho}{\lambda} \cdot \frac{\lambda - \gamma f + \chi(\lambda - f)}{1-\gamma} \cdot \frac{k_v}{q}
\end{aligned}$$

Subtracting the decentralized job-creation condition from the optimal gives:

$$\begin{aligned}
\left(\chi - \frac{\eta - \gamma}{1 - \eta} \right) \cdot \frac{1}{1 - \gamma} \cdot \frac{k_v}{q} &= \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{1 - \rho}{\lambda} \cdot \frac{b}{n} \\
&+ \frac{(1 - \rho)(\lambda - f)}{\lambda} \cdot \left(\chi - \frac{\eta - \gamma}{1 - \eta} \right) \cdot \frac{1}{1 - \gamma} \cdot \frac{k_v}{q}
\end{aligned}$$

Rearranging gives:

$$\begin{aligned}
\left(\chi - \frac{\eta - \gamma}{1 - \eta} \right) \cdot \frac{1}{1 - \gamma} \cdot \frac{k_v}{q} &= \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{\frac{1-\rho}{\lambda}}{\rho + (1-\rho) \cdot \frac{f}{\lambda}} \cdot \frac{b}{n} \\
&= \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{b}{f}
\end{aligned}$$

J.3 Lagrange Multipliers for Separation Condition

Optimal separation condition unconstrained firms

$$\begin{aligned}
& - \frac{\partial \mathcal{L}}{\partial \epsilon_s^u} \\
&= \frac{n}{1-\rho} \cdot (1-p) \cdot g(\epsilon_s^u) \cdot u'(c^w) \cdot \left(z(\epsilon_s^u) - \Omega(\epsilon_s^u) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w - (z + \Omega) \right) \\
&+ \lambda_\theta \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot \left[z(\epsilon_s^u) - \Omega(\epsilon_s^u) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right. \\
&\quad \left. - \frac{1-n}{n} \cdot b + \frac{\lambda - \eta f}{1 - \eta} \cdot \frac{k_v}{q} \right] \\
&+ \lambda_c \cdot \frac{\partial WE}{\partial \epsilon_s^u} + \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s \cdot \lambda_{n^u} + \lambda_{\epsilon_s^u} \cdot \frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial \epsilon_s^u} \stackrel{!}{=} 0
\end{aligned}$$

Insert for λ_{n^u} :

$$\begin{aligned}
\Longleftrightarrow & g(\epsilon_s^u) \cdot \frac{1-p}{\lambda} \cdot n^s \\
& \cdot \left[z(\epsilon_s^u) - \Omega(\epsilon_s^u) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w - (z + \Omega) + \frac{\lambda_{n^u}}{u'(c^w)} \right] \\
& - \frac{\lambda_\theta}{u'(c^w)} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot \left[s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u)) + \frac{1-n}{n} \cdot b \right] \\
& + \frac{\lambda_c}{u'(c^w)} \cdot \frac{\partial WE}{\partial \epsilon_s^u} + \frac{\lambda_{\epsilon_s^u}}{u'(c^w)} \cdot \frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial \epsilon_s^u} \stackrel{!}{=} 0
\end{aligned}$$

$$\begin{aligned}
\Longleftrightarrow & z(\epsilon_s^u) - \Omega(\epsilon_s^u) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + b + (\lambda - q(\theta) \cdot \theta) \cdot \frac{\lambda_{n^s}}{u'(c^w)} + \theta \cdot c \\
& - \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \cdot \left(s_{stw}(\bar{h} - h_{stw}(\epsilon_s^u)) + \frac{1-n}{n} \cdot b - \frac{b}{n} \right) \\
& + \lambda_c \cdot \frac{1}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial WE}{\partial \epsilon_s} \right) \\
& + \lambda_{\epsilon_s^u} \cdot \frac{1}{n^s \cdot u'(c^w)} \cdot \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial \epsilon_s^u} = 0
\end{aligned}$$

Insert for λ_{n^s} :

$$\begin{aligned}
\Longleftrightarrow & z(\epsilon_s^u) - \Omega(\epsilon_s^u) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + b \\
& + (\lambda - q(\theta) \cdot \theta) \cdot \frac{\lambda_{n^s}}{u'(c^w)} + \theta \cdot c \\
& - \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \cdot \left(s_{stw}(\bar{h} - h_{stw}(\epsilon_s^u)) + \frac{1-n}{n} \cdot b - \frac{b}{n} \right) \\
& + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial WE}{\partial \epsilon_s^u} \right) \\
& + \frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} \cdot \frac{1}{n^s} \cdot \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial \epsilon_s^u} = 0
\end{aligned}$$

Insert λ_{n^s}

$$\begin{aligned}
&\Longleftrightarrow z(\epsilon_s^u) - \Omega(\epsilon_s^u) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + b \\
&\quad + \frac{\lambda - \gamma f + \chi(\lambda - f)}{1 - \gamma} \cdot \frac{k_v}{q} \\
&\quad - \frac{\lambda_\theta}{n^s \cdot u'(c^w)} (s_{stw}(\bar{h} - h_{stw}(\epsilon_s^u)) - b) \\
&\quad + \lambda \cdot \frac{\lambda_c}{n^s \cdot u'(c^w)} \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{1 - p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial WE}{\partial \epsilon_s^u} \right) \\
&\quad + \frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} \cdot \frac{\lambda}{1 - p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial \epsilon_s^u} = 0
\end{aligned}$$

Subtract decentralized separation condition:

$$\begin{aligned}
s_{stw}(\bar{h} - h_{stw}(\epsilon_s^u)) &= b + (\lambda - \theta q(\theta)) \cdot \left(\chi - \frac{\eta - \gamma}{1 - \eta} \right) \cdot \frac{1}{1 - \gamma} \cdot \frac{k_v}{q} \\
&\quad + \frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} \cdot \frac{\lambda}{1 - p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial \epsilon_s^u} \\
&\quad - \frac{\lambda_\theta \cdot \theta}{n^s \cdot u'(c^w)} \cdot (s_{stw}(\bar{h} - h_{stw}(\epsilon_s^u)) - b) \\
&\quad + \frac{\lambda_c}{n^s \cdot u'(c^w)} \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{1 - p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial WE}{\partial \epsilon_s^u} \right)
\end{aligned}$$

Hence

$$\begin{aligned}
0 &= \left(1 + \frac{\lambda_\theta}{u'(c^w) \cdot n^s} \right) \\
&\quad \cdot \left(b + (\lambda - f) \cdot \frac{(1 - \rho/\lambda)}{(\rho + (1 - \rho) \cdot f/\lambda)} \cdot \frac{b}{n} - s_{stw}(\bar{h} - h_{stw}(\epsilon_s^u)) \right) \\
&\quad + \frac{\lambda}{1 - p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} \cdot \frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial \epsilon_s^u} \\
&\quad + \frac{\lambda_c}{n^s \cdot u'(c^w)} \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{1 - p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial WE}{\partial \epsilon_s^u} \right) \\
\Longleftrightarrow \quad 0 &= \left(1 + \frac{\lambda_\theta}{u'(c^w) \cdot n^s} \right) \cdot \left(\frac{\lambda}{f} \cdot b - s_{stw}(\bar{h} - h_{stw}(\epsilon_s^u)) \right) \\
&\quad + \frac{\lambda}{1 - p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} \cdot \frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial \epsilon_s^u} \\
&\quad + \frac{\lambda_c}{n^s \cdot u'(c^w)} \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{1 - p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial WE}{\partial \epsilon_s^u} \right)
\end{aligned}$$

And finally:

$$\begin{aligned}
-\frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} &= \frac{(1-p) \cdot g(\epsilon_s^u)}{\lambda} \cdot \frac{1}{\frac{\partial S_{\text{stw}}^u(\epsilon_s^u)}{\partial \epsilon_s^u}} \cdot \left(\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \right. \\
&\quad \cdot \left(\frac{\lambda}{f} \cdot b - s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^u)) \right) \\
&\quad \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{\lambda}{1-p} \cdot \frac{1}{g(\epsilon_s^u)} \cdot \frac{\partial WE}{\partial \epsilon_s^u} \right) \right)
\end{aligned}$$

Optimal separation condition constrained firms

$$\begin{aligned}
-\frac{\partial \mathcal{L}}{\partial \epsilon_s^c} &= \left[\frac{n}{1-\rho} \cdot p \cdot g(\epsilon_s^c) \cdot u'(c^w) (z(\epsilon_s^c) - \Omega(\epsilon_s^c)) \right. \\
&\quad \left. + \frac{u(c_{\text{stw}}(\epsilon_s^c))}{u'(c^w)} - c_{\text{stw}}(\epsilon_s^c) - (z + \Omega) \right) \\
&\quad + \lambda_\theta \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \left[z(\epsilon_s^c) - \Omega(\epsilon_s^c) + \frac{u(c_{\text{stw}}(\epsilon_s^c)) - u(b)}{u'(c^w)} - c^w(\epsilon_s^c) \right. \\
&\quad \left. - \frac{1-n}{n} \cdot b + \frac{\lambda - \eta f}{1-\eta} \cdot \frac{k_v}{q} \right] \\
&\quad \left. - \lambda_c \cdot \frac{\partial WE}{\partial \epsilon_s^c} + \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot \lambda_{n^c} \right] \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c) + \lambda_{\epsilon_s^c}^c \cdot \frac{\partial S_{\text{stw}}^u(\epsilon_s^c)}{\partial \epsilon_s^c} = 0
\end{aligned}$$

Subtract decentralized separation condition (constrained firms):

$$\begin{aligned}
-\frac{\partial \mathcal{L}}{\partial \epsilon_s^c} &= \left[\frac{n}{1-\rho} \cdot p \cdot g(\epsilon_s^c) \left(z_{\text{stw}}(\epsilon_s^c) - \Omega(\epsilon_s^c) + \frac{u(c_{\text{stw}}(\epsilon_s^c)) - u(c^w)}{u'(c^w)} - (z + \Omega) \right) \right. \\
&\quad + \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot \frac{\lambda_{n^c}}{u'(c^w)} \\
&\quad - \frac{\lambda_\theta}{u'(c^w)} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \left[s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^c)) + \frac{1-n}{n} \cdot b \right] \\
&\quad \left. + \frac{\lambda_c}{u'(c^w)} \cdot \frac{\partial WE}{\partial \epsilon_s^c} \right] \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c) + \frac{\lambda_{\epsilon_s^c}^c}{u'(c^w)} \cdot \frac{\partial S_{\text{stw}}^c(\epsilon_s^c)}{\partial \epsilon_s^c} = 0
\end{aligned}$$

Insert λ_{n^c} and λ_n

$$\begin{aligned}
\Longleftrightarrow -\frac{\partial \mathcal{L}}{\partial \epsilon_s^c} = & \left[\frac{p}{\lambda} \cdot n^s g(\epsilon_s^c) \left(z_{\text{stw}}(\epsilon_s^c) - \Omega(\epsilon_s^c) + \frac{u(c_{\text{stw}}(\epsilon_s^c))}{u'(c^w)} - u(c^w) - (z + \Omega) \right) \right. \\
& + \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot \left((\lambda - q(\theta) \cdot \theta) \cdot \frac{\lambda_{n^s}}{u'(c^w)} \right. \\
& + [z - \Omega + b + \theta \cdot c] - \frac{u(b)}{u'(c^w)} \\
& \left. \left. + \frac{1 - \rho}{\lambda} \cdot \frac{b}{n^2} \cdot \lambda_\theta \cdot \frac{1}{u'(c^w)} + \eta \cdot \frac{b}{n^2} \cdot \frac{\lambda_c}{u'(c^w)} \right) \right] \\
& - \frac{\lambda_\theta}{u'(c^w)} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \left[s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^c)) + \frac{1 - n}{n} \cdot b \right] \\
& + \frac{\lambda_c}{u'(c^w)} \cdot \frac{\partial W E}{\partial \epsilon_s^c} \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c) + \frac{\lambda_{\epsilon_s^c}^c}{u'(c^w)} \cdot \frac{\partial S_{\text{stw}}^c(\epsilon_s^c)}{\partial \epsilon_s^c} = 0
\end{aligned}$$

Insert λ_{n^s}

$$\begin{aligned}
-\frac{\partial \mathcal{L}}{\partial \epsilon_s^c} = & \left[z_{\text{stw}}(\epsilon_s^c) - \Omega(\epsilon_s^c) + \frac{u(c_{\text{stw}}(\epsilon_s^c))}{u'(c^w)} - c_{\text{stw}}(\epsilon_s^c) + b \right. \\
& + \frac{\lambda - \gamma \cdot f + \chi \cdot (\lambda - f)}{1 - \gamma} \cdot \frac{k_v}{q} \\
& - \frac{\lambda_\theta}{n^s \cdot u'(c^w)} [s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^c)) - b] \\
& \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial W E}{\partial \epsilon_s^c} \right) \right] \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \xi_s^c) \\
& + \frac{\lambda}{p} \cdot \frac{1}{n^s \cdot g(\epsilon_s^c)} \cdot \frac{\lambda_{\epsilon_s^c}^c}{u'(c^w)} \cdot \frac{\partial S_{\text{stw}}^c(\epsilon_s^c)}{\partial \epsilon_s^c} = 0
\end{aligned}$$

And finally:

$$\begin{aligned}
-\frac{\lambda_{\epsilon_s^c}^c}{n^s \cdot u'(c^w)} = & \frac{p}{\lambda} \cdot \frac{g(\epsilon_s^c)}{\frac{\partial s_{\text{stw}}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \cdot \left(\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \left(\frac{\lambda}{f} \cdot b - s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^c)) \right) \right. \\
& \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial W E}{\partial \epsilon_s^c} \right) \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c)
\end{aligned}$$

Analogously, it can be derived that

$$\begin{aligned}
-\frac{\lambda_{\xi_s^c}^c}{n^s \cdot u'(c^w)} = & \frac{p}{\lambda} \cdot \frac{g(\xi_s^c)}{\frac{\partial s_{\text{stw}}^c(\xi_s^c)}{\partial \xi_s^c}} \cdot \left(\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \left(\frac{\lambda}{f} \cdot b \right) \right. \\
& \left. + \frac{\lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\xi_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial W E}{\partial \xi_s^c} \right) \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \leq \xi_s^c)
\end{aligned}$$

J.4 Optimal STW Benefits

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial s_{stw}} &= \frac{p}{\lambda} \cdot n^s \cdot \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} (u'(c_{stw}(\epsilon)) - u'(c^w)) (\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
&\quad + \lambda_\theta \cdot \frac{p}{\lambda} \cdot \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} \left(\frac{u'(c_{stw}(\epsilon)) - u'(c^w)}{u'(c^w)} \right) (\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
&\quad - \frac{n^s \cdot (1 - \rho)}{\lambda} \cdot u'(c^w) \cdot \frac{\partial \Omega}{\partial s_{stw}} - \lambda_\theta \cdot \frac{(1 - \rho)}{\lambda} \cdot \frac{\partial \Omega}{\partial s_{stw}} - \lambda_c \cdot \frac{\partial WE}{\partial s_{stw}} \\
&\quad - \lambda_{\epsilon_s^u} \cdot \frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial s_{stw}} - \lambda_{\epsilon_s^c} \cdot \frac{\partial S_{stw}^c(\epsilon_s^c)}{\partial s_{stw}} = 0
\end{aligned}$$

Insert Lagrange multiplier separation condition:

$$\begin{aligned}
&\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right) \cdot \left(\frac{p}{\lambda} \int_{\epsilon_s^c}^{\max\{\epsilon_s^c, \epsilon_{stw}\}} \frac{u'(c_{stw}(\epsilon)) - u'(c^w)}{u'(c^w)} \cdot (\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \right. \\
&\quad \left. - (1 - \rho) \cdot \frac{\partial \Omega}{\partial s_{stw}}\right) - \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \frac{\partial WE}{\partial s_{stw}} \\
&\quad + \frac{(1 - p)}{\lambda} \cdot g(\epsilon_s^u) \cdot \frac{\partial \epsilon_s^u}{\partial s_{stw}} \cdot \left(\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right) \cdot \left(\frac{\lambda}{f} \cdot b - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u))\right) \right. \\
&\quad \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda}{1 - p} \cdot \frac{\partial WE}{\partial \epsilon_s^u}\right)\right) \\
&\quad + \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \frac{\partial \epsilon_s^c}{\partial s_{stw}} \cdot \left(\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right) \cdot \left(\frac{\lambda}{f} \cdot b - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^c))\right) \right. \\
&\quad \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \epsilon_s^c}\right)\right) = 0
\end{aligned}$$

Rearranging gives:

$$\begin{aligned}
\bar{\tau}_{stw} &= \underbrace{\frac{\lambda}{f} b}_{\text{Fiscal Ext.}} \\
&\quad + \underbrace{\frac{\mathbb{1}\{\epsilon_{stw} \geq \epsilon_s^c\}}{MMS_{stw}} \cdot n^s \cdot \frac{p}{\lambda} \int_{\epsilon_s^c}^{\epsilon_{stw}} \left(\frac{u'(c_{stw}(\epsilon)) - u'(c^w)}{u'(c^w)} \right) (\bar{h} - h_{stw}(\epsilon)) dG(\epsilon)}_{\text{Insurance}} \\
&\quad - \underbrace{\frac{n^s}{MMS_{stw}} \cdot \frac{1}{\lambda} \cdot (1 - \rho) \frac{\partial \Omega}{\partial s_{stw}}}_{\text{Distortion}} + \underbrace{BE_{stw,3}}_{\text{Bargaining Effect}} \\
\bar{\tau}_{stw} &= \frac{MMS_{stw}^u}{MMS_{stw}} s_{stw} (\bar{h} - h_{stw}(\epsilon_s^u)) \\
&\quad + \frac{MMS_{stw}^c}{MMS_{stw}} s_{stw} (\bar{h} - h_{stw}(\epsilon_s^c))
\end{aligned}$$

where

$$MMS_{stw}^u = \frac{(1-p)}{\lambda} \cdot g(\epsilon_s^u) \cdot \frac{\partial \epsilon_s^u}{\partial s_{stw}} \cdot n^s, \quad MMS_{stw}^c = \mathbb{1}(\epsilon_{stw} \geq \epsilon_s^c) \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \frac{\partial \epsilon_s^c}{\partial s_{stw}} \cdot n^s,$$

$$MMS_{stw} = MMS_{stw}^c + MMS_{stw}^u$$

and

$$\begin{aligned} BE_{stw,3} &= \frac{1}{\left(1 + \frac{\lambda_\theta}{n^s u'(c^w)}\right)} \\ &\times \left[-\frac{\lambda_c}{\varphi n^s u'(c^w)} \frac{\partial WE}{\partial s_{stw}} + \frac{MMS_{stw}^u}{MMS_{stw}} \frac{\lambda_c}{n^s u'(c^w)} \left(\eta \frac{b}{n} + \frac{1}{g(\epsilon_s^u)} \frac{\lambda}{1-p} \frac{\partial WE}{\partial \epsilon_s^u} \right) \right. \\ &\quad \left. + \frac{MMS_{stw}^c}{MMS_{stw}} \frac{\lambda_c}{n^s u'(c^w)} \left(\eta \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \frac{\lambda}{p} \frac{\partial WE}{\partial \epsilon_s^c} \right) \right] \end{aligned}$$

J.5 Optimal Eligibility Condition

Assumption throughout: $\epsilon^p \geq \epsilon_{stw} \geq \epsilon_s^u$

Further assume that:

$$n^s \cdot u'(c^w) + \lambda_\theta - \eta \cdot \lambda_c > 0, \quad n^s \cdot u'(c^w) + \lambda_\theta > 0$$

These conditions exclude the case that the Planner would want to use STW's hours distortions to destroy production and thus reduce vacancy posting. The Planner might want to do that when the Hosios condition is not fulfilled. For reasonable parameter values, however, the condition should hold anyway. Recall that by Lemma 1 $\epsilon_s^c > \epsilon_s^u$ and $\xi_s^c > \xi_s^u$.

Candidate I:

FOC for eligiblity threshold:

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial \epsilon_{\text{stw}}} &= g(\epsilon_{\text{stw}}) \cdot \frac{p}{\lambda} \cdot n^s \cdot \left(u(c_{\text{stw}}(\epsilon_{\text{stw}})) - u(c(\epsilon_{\text{stw}})) \right. \\
&\quad \left. - u'(c^w) \cdot [c_{\text{stw}}(\epsilon_{\text{stw}}) - c(\epsilon_{\text{stw}})] \right) \\
&\quad - n \cdot \frac{\partial \Omega}{\partial \epsilon_{\text{stw}}} \\
&\quad + \lambda_\theta \cdot \frac{p}{\lambda} \cdot \left(u(c_{\text{stw}}(\epsilon_{\text{stw}})) - u(c(\epsilon_{\text{stw}})) \right. \\
&\quad \left. - u'(c^w) \cdot [c_{\text{stw}}(\epsilon_{\text{stw}}) - c(\epsilon_{\text{stw}})] \right) \\
&\quad - \lambda_\theta \cdot \frac{1-\rho}{\lambda} \cdot \frac{\partial \Omega}{\partial \epsilon_{\text{stw}}} \\
&\quad - \lambda_c \cdot \frac{\partial WE}{\partial \epsilon_{\text{stw}}} \stackrel{!}{\geq} 0 \\
\\
\Leftrightarrow &\quad \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \left(\frac{1-\rho}{\lambda} \cdot n^s \cdot \frac{\partial \Omega}{\partial \epsilon_{\text{stw}}} + BE \right) \\
&\quad \stackrel{!}{\geq} \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \frac{p}{\lambda} \cdot g(\epsilon_{\text{stw}}) \cdot n^s \\
&\quad \cdot \left(\frac{u(c_{\text{stw}}(\epsilon_{\text{stw}})) - u(c(\epsilon_{\text{stw}}))}{\frac{c_{\text{stw}}(\epsilon_{\text{stw}}) - c(\epsilon_{\text{stw}})}{u'(c^w)}} - u'(c^w) \right) \\
&\quad \cdot [c_{\text{stw}}(\epsilon_{\text{stw}}) - c(\epsilon_{\text{stw}})] \\
\\
\Leftrightarrow &\quad \left(\frac{1-\rho}{\lambda} \cdot n^s \cdot \frac{\partial \Omega}{\partial \epsilon_{\text{stw}}} + BE \right) \stackrel{!}{\geq} \frac{p}{\lambda} \cdot g(\epsilon_{\text{stw}}) \cdot n^s \\
&\quad \cdot \left(\frac{u(c_{\text{stw}}(\epsilon_{\text{stw}})) - u(c(\epsilon_{\text{stw}}))}{\frac{c_{\text{stw}}(\epsilon_{\text{stw}}) - c(\epsilon_{\text{stw}})}{u'(c^w)}} - u'(c^w) \right) \\
&\quad \cdot [c_{\text{stw}}(\epsilon_{\text{stw}}) - c(\epsilon_{\text{stw}})]
\end{aligned}$$

If the equation holds with strict inequality, the cost of hours distortion exceeds the benefit of providing additional insurance to workers in constrained firms. Consequently, the Ramsey planner chooses not to allow firms and workers to enter short-time work when they could survive without reaching the threshold $\epsilon_{\text{stw}} = \xi_s^c$. Conversely, if the equation holds with exact equality, the participation threshold is determined by balancing the additional cost of hours distortions against the benefit of providing extra insurance.

Candidate II:

FOC for the eligibility threshold:

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial \epsilon_{\text{stw}}} &= -n^s \cdot u'(c^w) \cdot \frac{1-p}{\lambda} \cdot (1-\rho^u) \cdot \frac{\partial \Omega^u}{\partial \epsilon_{\text{stw}}} u'(c^w) \\
&\quad - (\lambda_\theta - \eta \cdot \lambda_c) \cdot \frac{1-p}{\lambda} \cdot (1-\rho^u) \cdot \frac{\partial \Omega^u}{\partial \epsilon_{\text{stw}}} \\
&= -(n^s \cdot u'(c^w) + \lambda_\theta + \eta \cdot \lambda_c) \cdot \frac{1-p}{\lambda} \cdot (1-\rho^u) \cdot \frac{\partial \Omega^u}{\partial \epsilon_{\text{stw}}}
\end{aligned}$$

Under reasonable parameter values (assuming that the Ramsey planner never wants to use short-time work to impede vacancy posting by destroying the efficiency of the match, captured by the Lagrange multipliers λ_θ and λ_c), we get:

$$\frac{\partial \mathcal{L}}{\partial \epsilon_{\text{stw}}} < 0 \quad \text{thus it is optimal to set} \quad \epsilon_{\text{stw}} = \epsilon_s^u.$$

Candidate III:

FOC for the eligibility threshold:

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial \epsilon_{\text{stw}}} &= -n^u \cdot \frac{\partial \Omega_u}{\partial \epsilon_{\text{stw}}} \cdot u'(c^w) \\
&\quad + \frac{n}{1-\rho} \cdot p \cdot g(\epsilon_{\text{stw}}) \cdot u'(c^w) \\
&\quad \cdot \left(z_{\text{stw}}(\epsilon_{\text{stw}}) + \frac{u(c_{\text{stw}}(\epsilon_{\text{stw}}))}{u'(c^w)} - c_{\text{stw}}(\epsilon_{\text{stw}}) - (z + \Omega) \right) \\
&\quad + \lambda_\theta \cdot \frac{(1-p)}{\lambda} \cdot (1-\rho^u) \cdot \frac{\partial \Omega_u}{\partial \epsilon_{\text{stw}}} \\
&\quad + \lambda_\theta \cdot \frac{p}{\lambda} \cdot g(\epsilon_{\text{stw}}) \\
&\quad \cdot \left[z(\epsilon_{\text{stw}}) + \frac{u(c_{\text{stw}}(\epsilon_{\text{stw}})) - u(b)}{u'(c^w)} \right. \\
&\quad \quad \left. - c_{\text{stw}}(\epsilon_{\text{stw}}) - \frac{1-n}{n} \cdot b + \frac{\lambda - \eta \cdot f}{1-\eta} \cdot \frac{k_v}{q} \right] \\
&\quad - \lambda_c \cdot \frac{\partial WE}{\partial \epsilon_{\text{stw}}} + \frac{p}{\lambda} \cdot g(\epsilon_{\text{stw}}) \cdot n^s \cdot \lambda_{n^c} \stackrel{!}{>} 0.
\end{aligned}$$

Insert n^u

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial \epsilon_{\text{stw}}} &= -n^s \cdot (1 - \rho^u) \cdot \left(\frac{1-p}{\lambda} \right) \cdot \frac{\partial \Omega_u}{\partial \epsilon_{\text{stw}}} \cdot u'(c^w) \\
&+ n^s \cdot \frac{p}{\lambda} \cdot g(\epsilon_{\text{stw}}) \cdot u'(c^w) \cdot \left(z_{\text{stw}}(\epsilon_{\text{stw}}) + \frac{u(c_{\text{stw}}(\epsilon_{\text{stw}}))}{u'(c^w)} \right) \\
&- n^s \cdot \frac{p}{\lambda} \cdot g(\epsilon_{\text{stw}}) \cdot u'(c^w) \cdot (c_{\text{stw}}(\epsilon_{\text{stw}}) + z + \Omega) \\
&+ \lambda_\theta \cdot \frac{g(\epsilon_{\text{stw}})}{\lambda} \cdot (1-p)(1-\rho^u) \cdot \frac{\partial \Omega_u}{\partial \epsilon_{\text{stw}}} \\
&+ \lambda_\theta \cdot \frac{p}{\lambda} \cdot g(\epsilon_{\text{stw}}) \cdot \left(z_{\text{stw}}(\epsilon_{\text{stw}}) + \frac{u(c_{\text{stw}}(\epsilon_{\text{stw}})) - u(b)}{u'(c^w)} - c_{\text{stw}}(\epsilon_{\text{stw}}) - \frac{1-n}{n} \cdot b \right. \\
&\quad \left. + \frac{\lambda - \eta \cdot f}{1-\eta} \cdot \left(\frac{k_v}{q} \right) \right) \\
&- \lambda_c \cdot \frac{\partial WE}{\partial \epsilon_{\text{stw}}} + \frac{p}{\lambda} \cdot g(\epsilon_{\text{stw}}) \cdot n^s \cdot \lambda_{n^c} \stackrel{!}{>} 0
\end{aligned}$$

$$\begin{aligned}
\Leftrightarrow & - (n^s \cdot u'(c^w) + \lambda_\theta) \cdot (1 - \rho^u) \cdot \left(\frac{1-p}{\lambda} \right) \cdot \frac{\partial \Omega_u}{\partial \epsilon_{\text{stw}}} \\
& + n^s \cdot \frac{p}{\lambda} \cdot g(\epsilon_{\text{stw}}) \cdot u'(c^w) \\
& \cdot \left(z_{\text{stw}}(\epsilon_{\text{stw}}) + \frac{u(c_{\text{stw}}(\epsilon_{\text{stw}}))}{u'(c^w)} - c_{\text{stw}}(\epsilon_{\text{stw}}) - (z + \Omega) + \frac{\lambda_{n^c}}{u'(c^w)} \right) \\
& + \lambda_\theta \cdot \frac{p}{\lambda} \cdot g(\epsilon_{\text{stw}}) \cdot \left[z_{\text{stw}}(\epsilon_{\text{stw}}) + \frac{u(c_{\text{stw}}(\epsilon_{\text{stw}})) - u(b)}{u'(c^w)} - c_{\text{stw}}(\epsilon_{\text{stw}}) \right. \\
& \quad \left. - \frac{1-n}{n} \cdot b + \frac{\lambda - \eta \cdot f}{1-\eta} \cdot \left(\frac{k_v}{q} \right) \right] \\
& - \lambda_c \cdot \frac{\partial WE}{\partial \epsilon_{\text{stw}}} \stackrel{!}{>} 0
\end{aligned}$$

Insert λ_{n^c} and subtract decentralized separation condition for constrained firms:

$$\begin{aligned}
\Leftrightarrow & - \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \frac{(1-p)}{\lambda} \cdot (1 - \rho^u) \cdot \frac{\partial \Omega_u}{\partial \epsilon_{\text{stw}}} \cdot \frac{1}{g(\epsilon_{\text{stw}})} \\
& + \frac{p}{\lambda} \cdot \left[b + z_{\text{stw}}(\epsilon_{\text{stw}}) + \frac{u(c_{\text{stw}}(\epsilon_{\text{stw}})) - u(b)}{u'(c^w)} - c_{\text{stw}}(\epsilon_{\text{stw}}) \right. \\
& \quad \left. + \frac{\lambda - \eta \cdot f + \chi \cdot (\lambda - f)}{1-\eta} \cdot \left(\frac{k_v}{q} \right) \right] \\
& - \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \cdot \frac{p}{\lambda} \cdot [s_{\text{stw}} \cdot (h - h_{\text{stw}}(\epsilon_{\text{stw}})) - b] \\
& - \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\frac{\partial WE}{\partial \epsilon_{\text{stw}}} \cdot \frac{1}{g(\epsilon_{\text{stw}})} \cdot \frac{\partial S_{\text{stw}}(\epsilon_{\text{stw}})}{\partial \epsilon_{\text{stw}}} + \frac{p}{\lambda} \cdot \eta \cdot \frac{b}{n} \right) \stackrel{!}{>} 0
\end{aligned}$$

Subtract decentralized separation condition:

$$\begin{aligned}
\Leftrightarrow & - \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \frac{(1-p)}{\lambda} \cdot (1-\rho^u) \cdot \frac{\partial \Omega_u}{\partial \epsilon_{\text{stw}}} \cdot \frac{1}{g(\epsilon_{\text{stw}})} \\
& + \frac{p}{\lambda} \cdot \left[z_{\text{stw}}(\epsilon_{\text{stw}}) - z_{\text{stw}}(\epsilon_s) + \frac{u(c_{\text{stw}}(\epsilon_{\text{stw}})) - u(c_{\text{stw}}(\epsilon_s^c))}{u'(c^w)} \right. \\
& \quad \left. - s_{\text{stw}} \cdot (h - h_{\text{stw}}(\epsilon_s^c)) + b + (1-\rho) \cdot (\lambda - f) \cdot \left(\chi - \frac{\eta - \gamma}{1 - \gamma} \right) \cdot \frac{1}{1 - \gamma} \cdot \frac{k_v}{q} \right] \\
& + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \cdot \frac{p}{\lambda} \cdot \left[z_{\text{stw}}(\epsilon_{\text{stw}}) - z_{\text{stw}}(\epsilon_s^c) + \frac{u(c_{\text{stw}}(\epsilon_{\text{stw}})) - u(c_{\text{stw}}(\epsilon_s^c))}{u'(c^w)} \right. \\
& \quad \left. - s_{\text{stw}} \cdot (h - h_{\text{stw}}(\epsilon_s^c)) + b \right] \\
& - \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\frac{\partial W E}{\partial \epsilon_{\text{stw}}} \cdot \frac{1}{g(\epsilon_{\text{stw}})} \cdot \frac{\partial S_{\text{stw}}(\epsilon_{\text{stw}})}{\partial \epsilon_{\text{stw}}} + \frac{p}{\lambda} \cdot \eta \cdot \frac{b}{n} \right) \stackrel{!}{>} 0
\end{aligned}$$

Inserting for $(\chi - \frac{\eta - \gamma}{1 - \gamma}) \cdot \frac{1}{1 - \gamma} \cdot \frac{k_v}{q}$ gives us the final condition. We can distinguish between three cases:

(A)

$$\begin{aligned}
& g(\epsilon_{\text{stw}}) \cdot \frac{p}{\lambda} \cdot n^s \cdot \left[z_{\text{stw}}(\epsilon_{\text{stw}}) - z_{\text{stw}}(\epsilon_s^c) \right. \\
& \quad \left. + \frac{u(c_{\text{stw}}(\epsilon_{\text{stw}})) - u(c_{\text{stw}}(\epsilon_s^c))}{u'(c^w)} + \frac{\lambda}{f} \cdot b - s_{\text{stw}} \cdot (h - h_{\text{stw}}(\epsilon_s^c)) \right] \\
& > n^s \cdot \frac{1-p}{\lambda} \cdot (1-\rho) \cdot \frac{\partial \Omega_u}{\partial \epsilon_{\text{stw}}} + B E \\
\forall \epsilon_{\text{stw}} \text{ in case 3} & \Rightarrow \epsilon_{\text{stw}} = \xi_s^c
\end{aligned}$$

(B)

$$\begin{aligned}
& g(\epsilon_{\text{stw}}) \cdot \frac{p}{\lambda} \cdot n^s \cdot \left[z_{\text{stw}}(\epsilon_{\text{stw}}) - z_{\text{stw}}(\epsilon_s^c) \right. \\
& \quad \left. + \frac{u(c_{\text{stw}}(\epsilon_{\text{stw}})) - u(c_{\text{stw}}(\epsilon_s^c))}{u'(c^w)} + \frac{\lambda}{f} \cdot b - s_{\text{stw}} \cdot (h - h_{\text{stw}}(\epsilon_s^c)) \right] \\
& < n^s \cdot \frac{1-p}{\lambda} \cdot (1-\rho) \cdot \frac{\partial \Omega_u}{\partial \epsilon_{\text{stw}}} + B E \\
\forall \epsilon_{\text{stw}} \text{ in case 3} & \Rightarrow \epsilon_{\text{stw}} = \max\{\xi_s^c, \xi_s^u\}
\end{aligned}$$

(C)

$$\begin{aligned}
& g(\epsilon_{\text{stw}}) \cdot \frac{p}{\lambda} \cdot n^s \cdot \left[z_{\text{stw}}(\epsilon_{\text{stw}}) - z_{\text{stw}}(\epsilon_s^c) \right. \\
& \quad \left. + \frac{u(c_{\text{stw}}(\epsilon_{\text{stw}})) - u(c_{\text{stw}}(\epsilon_s^c))}{u'(c^w)} + \frac{\lambda}{f} \cdot b - s_{\text{stw}} \cdot (h - h_{\text{stw}}(\epsilon_s^c)) \right] \\
& = n^s \cdot \frac{1-p}{\lambda} \cdot (1-\rho) \cdot \frac{\partial \Omega_u}{\partial \epsilon_{\text{stw}}} + BE
\end{aligned}$$

BE is defined as:

$$\begin{aligned}
BE & = g(\epsilon_{\text{stw}}) \cdot \frac{\lambda_c}{u'(c^w)} \cdot \left(\frac{\partial WE}{\partial \epsilon_{\text{stw}}} \cdot \frac{1}{g(\epsilon_{\text{stw}})} \cdot \frac{\partial S_{\text{stw}}(\epsilon_{\text{stw}})}{\partial \epsilon_{\text{stw}}} + \eta \cdot \frac{b}{n} \right) \\
& \quad \Bigg/ \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right)
\end{aligned}$$

This concludes the proof of Proposition 4.

J.6 Optimal Unemployment Insurance with STW

From the FOC of UI, we can derive the optimality condition of unemployment insurance:

$$\begin{aligned}
(1-n) \cdot (u'(b) - u'(c^w)) & = \lambda_\theta (1-\rho) \cdot \left(\frac{1-n}{n} + \frac{u'(b)}{u'(c^w)} \right) \\
& \quad + (\lambda_{\epsilon_s^u} + \lambda_{\epsilon_s^c} + \lambda_{\xi_s^c}) \cdot \left(-\frac{u'(b)}{u'(c^w)} \right) \\
& \quad + \lambda_c (1-\rho) \cdot \left(\eta \cdot \frac{1-n}{n} - (1-\eta) \cdot \frac{u'(b)}{u'(c^w)} \right)
\end{aligned}$$

To get better insight, we need to determine the Lagrange multipliers for λ_θ , λ_c . We

already know the Lagrange multipliers for the separation conditions:

$$\begin{aligned}
-\frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} &= \frac{1-p}{\lambda} \cdot \frac{g(\epsilon_s^u)}{\frac{\partial S_{\text{stw}}^u(\epsilon_s^u)}{\partial \epsilon_s^u}} \\
&\quad \cdot \left(\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \left(\frac{\lambda}{f} \cdot b - s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^u)) \right) \right. \\
&\quad \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda}{1-p} \cdot \frac{\partial WE}{\partial \epsilon_s^u} \right) \right) \\
-\frac{\lambda_{\xi_s^c}}{n^s \cdot u'(c^w)} &= \frac{p}{\lambda} \cdot \frac{g(\xi_s^c)}{\frac{\partial S_{\text{stw}}^c(\xi_s^c)}{\partial \xi_s^c}} \cdot \left(\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \frac{\lambda}{f} \cdot b \right. \\
&\quad \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\xi_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \xi_s^c} \right) \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \leq \xi_s^c) \\
-\frac{\lambda_{\epsilon_s^c}}{n^s \cdot u'(c^w)} &= \frac{p}{\lambda} \cdot \frac{g(\epsilon_s^c)}{\frac{\partial S_{\text{stw}}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \cdot \left(\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \left(\frac{\lambda}{f} \cdot b - s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^c)) \right) \right. \\
&\quad \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \epsilon_s^c} \right) \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c)
\end{aligned}$$

First, let us find an expression for λ_c :

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial c^w} &= - \left[(1-p) \cdot (1-\rho^u) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right. \\
&\quad \left. + p \cdot (1-\rho^c) \cdot \frac{u^c - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right] \cdot \lambda_\theta \\
&\quad - (1-\eta) \cdot (1-p) \cdot (1-\rho^u) \cdot \left(1 - (1-\eta) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right) \\
&\quad - (1-p) \cdot (1-\rho^c) \cdot (1-\eta) \cdot \frac{u^c - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \cdot \lambda_c \\
&\quad + \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \cdot \lambda_{\epsilon_s^u} \\
&\quad + \frac{u(c(\xi_s^c)) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \cdot \lambda_{\xi_s^c} \\
&\quad + \frac{u(c_{\text{stw}}(\epsilon_s^c)) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \cdot \lambda_{\epsilon_s^c} = 0
\end{aligned}$$

Insert Lagrange multipliers for separation conditions

$$\begin{aligned}
& - \left(p(1 - \rho^u) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} + (1 - p)(1 - \rho^c) \cdot \frac{u^c - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right) \lambda_\theta \\
& - (1 - \eta) \cdot \left((1 - p) \cdot (1 - \rho^u) \cdot \left(1 - (1 - \eta) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right) \right. \\
& \left. - p \cdot (1 - \rho^c) \cdot (1 - \eta) \cdot \frac{u^c - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right) \lambda_c \\
& + \frac{\partial \epsilon_s^u}{\partial c^w} \cdot \frac{1 - p}{\lambda} \cdot g(\epsilon_s^u) (n^s \cdot u'(c^w) + \lambda_\theta) \cdot \left(\frac{\lambda}{f} \cdot b - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u)) \right) \\
& + \lambda_c \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda}{1 - p} \cdot \frac{\partial WE}{\partial \epsilon_s^u} \right) \\
& + \frac{\partial \xi_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\xi_s^c) (n^s \cdot u'(c^w) + \lambda_\theta) \cdot \left(\frac{\lambda}{f} \cdot b + \lambda_c \cdot \left(\eta \cdot \frac{b}{n} - \frac{1}{g(\xi_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \xi_s^c} \right) \right) \\
& \cdot \mathbb{1}(\epsilon_{stw} \leq \xi_s^c) \\
& + \frac{\partial \xi_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\xi_s^c) (n^s \cdot u'(c^w) + \lambda_\theta) \cdot \left(\frac{\lambda}{f} \cdot b - s_{stw} \cdot (\bar{h} - h_{stw}(\xi_s^c)) \right) \\
& + \lambda_c \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\xi_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \xi_s^c} \right) \cdot \mathbb{1}(\epsilon_{stw} \geq \epsilon_s^c) = 0
\end{aligned}$$

Rearranging yields

$$\begin{aligned}
0 &= \lambda_\theta \cdot \frac{\partial S^{\text{total}}}{\partial c^w} + \lambda_c \cdot \frac{\partial WE^{\text{total}}}{\partial c^w} \\
&+ \frac{\partial \epsilon_s^u}{\partial c^w} \cdot \frac{1 - p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s \cdot u'(c^w) \cdot \left(\frac{\lambda}{f} \cdot b - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u)) \right) \\
&+ \frac{\partial \xi_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\xi_s^c) \cdot n^s \cdot u'(c^w) \cdot \frac{\lambda}{f} \cdot b \cdot \mathbb{1}(\epsilon_{stw} \leq \xi_s^c) \\
&+ \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot u'(c^w) \cdot \left(\frac{\lambda}{f} \cdot b - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{stw} \geq \epsilon_s^c)
\end{aligned}$$

with

$$\begin{aligned}
\frac{\partial S^{\text{total}}}{\partial c^w} &= (1 - p) \cdot (1 - \rho^u) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \\
&- p \cdot (1 - \rho^c) \cdot \frac{u^c - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \\
&+ \frac{\partial \epsilon_s^u}{\partial c^w} \cdot \frac{1 - p}{\lambda} \cdot g(\epsilon_s^u) \cdot \left(\frac{\lambda}{f} b - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u)) \right) \\
&+ \frac{\partial \xi_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\xi_s^c) \cdot \frac{\lambda}{f} \cdot b \cdot \mathbb{1}(\epsilon_{stw} \leq \xi_s^c) \\
&+ \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \left(\frac{\lambda}{f} b - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{stw} \geq \epsilon_s^c)
\end{aligned}$$

and

$$\begin{aligned}
\frac{\partial WE^{\text{total}}}{\partial c^w} &= -(1-\eta) \cdot (1-p) \cdot (1-\rho^u) \cdot \left(1 - (1-\eta) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \right) \\
&+ p \cdot (1-\rho^c) \cdot (1-\eta) \cdot \frac{u^c - u(b)}{u'(c^w)} \cdot \frac{u''(c^w)}{u'(c^w)} \\
&+ \frac{\partial \epsilon_s^u}{\partial c^w} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot \lambda_c \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda}{1-p} \cdot \frac{\partial WE}{\partial \epsilon_s^u} \right) \\
&+ \frac{\partial \xi_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\xi_s^c) \cdot \lambda_c \cdot \left(\eta \cdot \frac{b}{n} - \frac{1}{g(\xi_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \epsilon_s^c} \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \leq \xi_s^c) \\
&+ \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \lambda_c \cdot \left(\eta \cdot \frac{b}{n} - \frac{1}{g(\epsilon_s^c)} \cdot \frac{1}{p} \cdot \frac{\partial WE}{\partial \epsilon_s^c} \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c)
\end{aligned}$$

Collecting terms:

$$\begin{aligned}
\lambda_c &= \frac{-1}{\left(\frac{\partial WE}{\partial c^w}\right)^{\text{total}}} \left[\frac{\partial \epsilon_s^u}{\partial c^w} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s \cdot u'(c^w) \left(\frac{\lambda}{f} \cdot b - s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^u)) \right) \right. \\
&+ \frac{\partial \xi_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\xi_s^c) \cdot n^s \cdot u'(c^w) \left(\frac{\lambda}{f} \cdot b \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \leq \xi_s^c) \\
&+ \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot u'(c^w) \left(\frac{\lambda}{f} \cdot b - s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c) \\
&\left. + \left(-\frac{\partial S_{\text{total}}}{\partial c^w} \right) \cdot \lambda_\theta \right]
\end{aligned}$$

Insert λ_c into the Lagrange multipliers for the separation conditions. To do that, let us

rewrite the Lagrange multipliers of the separation conditions:

$$\begin{aligned}
\lambda_{\epsilon_s^u} &= -\frac{1}{\frac{\partial S_{\text{stw}}^u(\epsilon_s^u)}{\partial \epsilon_s^u}} \left(n^s \cdot u'(c^w) \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^u) \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \right. \\
&\quad \cdot \left(\frac{\lambda}{f} \cdot b - s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^u)) \right) \\
&\quad \left. + \lambda_c \left(\left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) \cdot \left(-\frac{\partial W E}{\partial n} \right) + \frac{\partial W E}{\partial \epsilon_s^u} \right) \right) \\
\lambda_{\xi_s^c} &= \frac{\mathbb{1}(\epsilon_{\text{stw}} \leq \xi_s^c)}{\frac{\partial S_{\text{stw}}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \left(n^s \cdot u'(c^w) \cdot \frac{p}{\lambda} \cdot g(\xi_s^c) \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \frac{\lambda}{f} \cdot b \right. \\
&\quad \left. + \lambda_c \left(\frac{\partial n}{\partial \xi_s^c} \cdot \left(-\frac{\partial W E}{\partial n} \right) + \frac{\partial W E}{\partial \xi_s^c} \right) \right) \\
\lambda_{\epsilon_s^c} &= -\frac{\mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c)}{\frac{\partial S_{\text{stw}}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \left(n^s \cdot u'(c^w) \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \right. \\
&\quad \cdot \left(\frac{\lambda}{f} \cdot b - s_{\text{stw}} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^c)) \right) \\
&\quad \left. + \lambda_c \left(\left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot \left(-\frac{\partial W E}{\partial n} \right) + \frac{\partial W E}{\partial \epsilon_s^c} \right) \right)
\end{aligned}$$

Inserting λ_c gives:

$$\begin{aligned}
\lambda_{\epsilon_s^u} &= \\
&- \frac{1}{\frac{\partial S_{\text{stw}}^u(\epsilon_s^u)}{\partial \epsilon_s^u}} \left[n^s u'(c^w) \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \left(\frac{\lambda}{f} b - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^u)) \right) \right. \\
&\quad + \left(\left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) \left(-\frac{\partial c^w}{\partial n} \right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^u} \right)^{\text{total}} \right) \\
&\quad \cdot \left(\frac{\partial \epsilon_s^u}{\partial c^w} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s u'(c^w) \left(\frac{\lambda}{f} b - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^u)) \right) \right. \\
&\quad + \frac{\partial \xi_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\xi_s^c) \cdot n^s u'(c^w) \cdot \frac{\lambda}{f} b \cdot \mathbb{1}(\epsilon_{\text{stw}} \leq \xi_s^c) \\
&\quad + \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s u'(c^w) \left(\frac{\lambda}{f} b - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c) \\
&\quad \left. \left. + \left(-\frac{\partial S^{\text{total}}}{\partial c^w} \right) \cdot \lambda_\theta \right) \right]
\end{aligned}$$

$$\begin{aligned}
\lambda_{\xi_s^c} = & \frac{\mathbb{1}(\epsilon_{\text{stw}} \leq \xi_s^c)}{\frac{\partial S_{\text{stw}}^c(\xi_s^c)}{\partial \xi_s^c}} \left[-n^s u'(c^w) \cdot \frac{p}{\lambda} \cdot g(\xi_s^c) \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \left(\frac{\lambda}{f} b - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\xi_s^c)) \right) \right. \\
& + \left(\left(-\frac{\partial n^c}{\partial \xi_s^c} \right) \left(-\frac{\partial c^w}{\partial n} \right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \xi_s^c} \right)^{\text{total}} \right) \\
& \cdot \left(\frac{\partial \epsilon_s^u}{\partial c^w} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s u'(c^w) \left(\frac{\lambda}{f} b - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^u)) \right) \right. \\
& + \frac{\partial \xi_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\xi_s^c) \cdot n^s u'(c^w) \cdot \frac{\lambda}{f} b \cdot \mathbb{1}(\epsilon_{\text{stw}} \leq \xi_s^c) \\
& + \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s u'(c^w) \left(\frac{\lambda}{f} b - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c) \\
& \left. \left. + \left(-\frac{\partial S^{\text{total}}}{\partial c^w} \right) \cdot \lambda_\theta \right) \right]
\end{aligned}$$

$$\begin{aligned}
\lambda_{\epsilon_s^c} = & -\frac{\mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c)}{\frac{\partial S_{\text{stw}}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \left[n^s u'(c^w) \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \left(\frac{\lambda}{f} b - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^c)) \right) \right. \\
& + \left(\left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \left(-\frac{\partial c^w}{\partial n} \right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^c} \right)^{\text{total}} \right) \\
& \cdot \left(\frac{\partial \epsilon_s^u}{\partial c^w} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s u'(c^w) \left(\frac{\lambda}{f} b - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^u)) \right) \right. \\
& + \frac{\partial \xi_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\xi_s^c) \cdot n^s u'(c^w) \cdot \frac{\lambda}{f} b \cdot \mathbb{1}(\epsilon_{\text{stw}} \leq \xi_s^c) \\
& + \frac{\partial \epsilon_s^c}{\partial c^w} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s u'(c^w) \left(\frac{\lambda}{f} b - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c) \\
& \left. \left. + \left(-\frac{\partial S^{\text{total}}}{\partial c^w} \right) \cdot \lambda_\theta \right) \right]
\end{aligned}$$

Now we have everything to calculate λ_θ from two equations:

$$\begin{aligned}
(1) \quad & \left(\chi - \frac{\eta - \gamma}{1 - \eta} \right) \cdot \frac{1}{1 - \gamma} \cdot \frac{k_v}{q} \\
& = \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{b}{f} \\
(2) \quad & \chi = \frac{1}{1 - \eta} \cdot \frac{1}{u \cdot f} \cdot \frac{1}{u'(c^w)} \cdot \left[\gamma - (\lambda\gamma - f\eta) \cdot \left(\frac{1}{\lambda} (1 - \rho) \lambda_\theta - \lambda_{\epsilon_s^u} \right) \right] \\
& + \frac{1}{u} \cdot \frac{1}{u'(c^w)} \cdot \left(\lambda \cdot \frac{\gamma}{f} \cdot u'(c^w) + \left(\frac{1}{1 - \eta} \cdot \frac{\lambda\gamma - f}{f} \right) \cdot \eta \right) \cdot \lambda_{\epsilon_s^c} \\
& + \frac{1}{u} \cdot \frac{1}{u'(c^w)} \cdot \left(\lambda \cdot \frac{\gamma}{f} \cdot u'(c^w) + \left(\frac{1}{1 - \eta} \cdot \frac{\lambda\gamma - f}{f} \right) \cdot \eta \right) \cdot \lambda_{\epsilon_s^c} \\
& + \frac{1}{u} \cdot \frac{1}{u'(c^w)} \cdot \lambda_c \cdot \frac{\partial WE}{\partial \theta} \cdot \frac{1}{k_v} \\
& - \frac{1}{u} \cdot \frac{1}{u'(c^w)} \cdot IE_\theta
\end{aligned}$$

We can rearrange (1) to:

$$\chi \cdot k_v = (1 - \gamma) \cdot q \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{b}{f} \right)$$

Note that

$$(1 - \gamma) \cdot q = -\frac{\partial f}{\partial \theta}$$

with

$$\begin{aligned}
f'(\theta) &= q(\theta) + \theta \cdot q'(\theta) \\
&= q(\theta) \cdot \left(1 + \frac{q'(\theta) \cdot \theta}{q(\theta)} \right) \\
&= q(\theta) \cdot (1 - \gamma)
\end{aligned}$$

Inserting χ gives:

$$\begin{aligned}
& [\gamma - (\lambda\gamma - f \cdot \eta)] \cdot \frac{1}{\lambda} \cdot (1 - \rho) \cdot \frac{1}{1 - \eta} \cdot \frac{k_v}{f} \cdot \lambda_\theta \\
&= u'(c^w) \cdot \left(\frac{\partial f}{\partial \theta} \right) \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta + \eta \cdot \lambda \cdot \lambda_c}{n^s \cdot u'(c^w)} \right) \cdot \frac{b}{f} \right) \\
&\quad + \frac{1}{f} \cdot (\lambda\gamma - f \cdot \eta) \cdot k_v \cdot (-\lambda_{\epsilon_s^u}) \\
&\quad + \left(\lambda \cdot \frac{\gamma}{f} \cdot u'(c^w(\epsilon_s^c)) + \left(\frac{1}{1 - n} \cdot \frac{\lambda\gamma - f}{f} \right) \cdot \eta \right) \cdot k_v \cdot (-\lambda_{\xi_s^c}) \\
&\quad + \left(\lambda \cdot \frac{\gamma}{f} \cdot u'(c(\xi_s^c)) + \left(\frac{1}{1 - n} \cdot \frac{\lambda\gamma - f}{f} \right) \cdot \eta \right) \cdot k_v \cdot (-\lambda_{\epsilon_s^c}) \\
&\quad + \frac{\partial WE}{\partial \theta} \cdot (-\lambda_c) \\
&\quad + IE_\theta
\end{aligned}$$

Insert $\lambda_{\epsilon_s^u}, \lambda_{\epsilon_s^c}, \lambda_{\xi_s^c}, IE_\theta$:

$$\begin{aligned}
& \left[\gamma - (\lambda\gamma - f \cdot \eta) \cdot \frac{1}{\lambda} \cdot (1 - \rho) \right] \cdot \frac{1}{1 - \eta} \cdot \frac{k_v}{f} \cdot \lambda_\theta \\
&= u'(c^w) \cdot \left(\frac{\partial f}{\partial \theta} \right) \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \cdot \frac{b}{f} \right) \\
&\quad + u'(c^w) \cdot n^s \cdot \left(-\frac{\partial \epsilon_s^u}{\partial \theta} \right)^{\text{total}} \cdot g(\epsilon_s^u) \\
&\quad \cdot \frac{1 - p}{\lambda} \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \left(\frac{\lambda}{f} b - s_{stw}(\bar{h} - h_{stw}(\epsilon_s^u)) \right) \\
&\quad + u'(c^w) \cdot n^s \cdot \left(-\frac{\partial \xi_s^c}{\partial \theta} \right)^{\text{total}} \cdot g(\xi_s^c) \cdot \frac{p}{\lambda} \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \cdot \frac{\lambda}{f} b \cdot \mathbb{1}(\epsilon_{stw} \leq \xi_s^c) \\
&\quad + u'(c^w) \cdot n^s \cdot \left(-\frac{\partial \epsilon_s^c}{\partial \theta} \right)^{\text{total}} \cdot g(\epsilon_s^c) \\
&\quad \cdot \frac{p}{\lambda} \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \left(\frac{\lambda}{f} b - s_{stw}(\bar{h} - h_{stw}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{stw} \geq \epsilon_s^c) \\
&\quad + \lambda_\theta \cdot \left(-\frac{\partial c^w}{\partial \theta} \right)^{\text{total}} \cdot \left(-\frac{\partial S}{\partial c^w} \right)^{\text{total}} \\
&\quad + n^s \cdot u'(c^w) \cdot \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \cdot \tilde{IE}_\theta
\end{aligned}$$

Denote:

$$\begin{aligned}
\left(-\frac{\partial \epsilon_s^u}{\partial \theta}\right)^{\text{total}} &= \left(-\frac{\partial \epsilon_s^u}{\partial \theta}\right) + \left(\frac{\partial c^w}{\partial \theta}\right)^{\text{total}} \cdot \left(-\frac{\partial \epsilon_s^u}{\partial c^w}\right) \\
&\quad + \left(-\frac{\partial \epsilon_s^u}{\partial \theta}\right) \cdot \left[\left(-\frac{\partial n^u}{\partial \epsilon_s^u}\right) \cdot \left(-\frac{\partial c^w}{\partial n}\right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^u}\right)^{\text{total}}\right] \cdot \left(\frac{\partial \epsilon_s^u}{\partial c^w}\right) \\
&\quad + f'(\theta) \cdot \frac{\partial n}{\partial f} \cdot \frac{\partial c^w}{\partial n} \cdot \frac{\partial \epsilon_s^u}{\partial c^w} \\
\left(-\frac{\partial \xi_s^c}{\partial \theta}\right)^{\text{total}} &= \left[\left(-\frac{\partial \xi_s^c}{\partial \theta}\right) + \left(\frac{\partial c^w}{\partial \theta}\right)^{\text{total}} \cdot \left(-\frac{\partial \xi_s^c}{\partial c^w}\right)\right. \\
&\quad \left.+ \left(-\frac{\partial \xi_s^c}{\partial \theta}\right) \cdot \left[\left(-\frac{\partial n^c}{\partial \xi_s^c}\right) \cdot \left(-\frac{\partial c^w}{\partial n}\right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \xi_s^c}\right)^{\text{total}}\right] \cdot \left(\frac{\partial \xi_s^c}{\partial c^w}\right)\right. \\
&\quad \left.+ f'(\theta) \cdot \frac{\partial n}{\partial f} \cdot \frac{\partial c^w}{\partial n} \cdot \frac{\partial \xi_s^c}{\partial c^w}\right] \cdot \mathbb{1}(\epsilon_{\text{stw}} \leq \xi_s^c) \\
\left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right)^{\text{total}} &= \left[\left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right) + \left(\frac{\partial c^w}{\partial \theta}\right)^{\text{total}} \cdot \left(-\frac{\partial \epsilon_s^c}{\partial c^w}\right)\right. \\
&\quad \left.+ \left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right) \cdot \left[\left(-\frac{\partial n^c}{\partial \epsilon_s^c}\right) \cdot \left(-\frac{\partial c^w}{\partial n}\right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^c}\right)^{\text{total}}\right] \cdot \frac{\partial \epsilon_s^c}{\partial c^w}\right. \\
&\quad \left.+ f'(\theta) \cdot \frac{\partial n}{\partial f} \cdot \frac{\partial c^w}{\partial n} \cdot \frac{\partial \epsilon_s^c}{\partial c^w}\right] \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c) \\
\left(-\frac{\partial c^w}{\partial \theta}\right)^{\text{total},2} &= \left(-\frac{\partial c^w}{\partial \theta}\right)^{\text{total}} \\
&\quad + \left(-\frac{\partial \epsilon_s^u}{\partial \theta}\right) \cdot \left[\left(-\frac{\partial n^u}{\partial \epsilon_s^u}\right) \cdot \left(-\frac{\partial c^w}{\partial n}\right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^u}\right)^{\text{total}}\right] \\
&\quad + \left(-\frac{\partial \xi_s^c}{\partial \theta}\right) \cdot \left[\left(-\frac{\partial n^c}{\partial \xi_s^c}\right) \cdot \left(-\frac{\partial c^w}{\partial n}\right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \xi_s^c}\right)^{\text{total}}\right] \\
&\quad + \left(-\frac{\partial \epsilon_s^c}{\partial \theta}\right) \cdot \left[\left(-\frac{\partial n^c}{\partial \epsilon_s^c}\right) \cdot \left(-\frac{\partial c^w}{\partial n}\right)^{\text{total}} + \left(\frac{\partial c^w}{\partial \epsilon_s^c}\right)^{\text{total}}\right] \\
&\quad + f'(\theta) \cdot \frac{\partial n}{\partial f} \cdot \frac{\partial c^w}{\partial n}
\end{aligned}$$

This allows us to calculate the Lagrange multiplier for the job-creation condition:

$$\begin{aligned}
M \cdot \lambda_\theta = & \\
& u'(c^w) \cdot \frac{\partial f}{\partial \theta} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \cdot \frac{b}{f} \right) \\
& + u'(c^w) \cdot n^s \cdot \left(\frac{\partial \epsilon_s^u}{\partial \theta} \right)^{\text{total}} \cdot g(\epsilon_s^u) \cdot \frac{1 - p}{\lambda} \left(\frac{\lambda}{f} b - s_{stw}(\bar{h} - h_{stw}(\epsilon_s^u)) \right) \\
& + u'(c^w) \cdot n^s \cdot \left(-\frac{\partial \xi_s^c}{\partial \theta} \right)^{\text{total}} \cdot g(\xi_s^c) \cdot \frac{p}{\lambda} \cdot \frac{\lambda}{f} b \cdot \mathbb{1}(\epsilon_{stw} \leq \xi_s^c) \\
& + u'(c^w) \cdot n^s \cdot \left(-\frac{\partial \epsilon_s^c}{\partial \theta} \right)^{\text{total}} \cdot g(\epsilon_s^c) \\
& \cdot \frac{p}{\lambda} \left(\frac{\lambda}{f} b - s_{stw}(\bar{h} - h_{stw}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{stw} \geq \epsilon_s^c) \\
& + u'(c^w) \cdot n^s \cdot \tilde{I} E_\theta
\end{aligned}$$

with

$$\begin{aligned}
M = & \left[\gamma - (\lambda \gamma - f \cdot \eta) \cdot \frac{1}{\lambda} \cdot (1 - \rho) \right] \cdot \frac{1}{1 - \eta} \cdot \frac{k_v}{f} \\
& + \left(-\frac{\partial f}{\partial \theta} \cdot u \cdot \frac{b}{f} \right) \\
& + \left(\frac{\partial \epsilon_s^u}{\partial \theta} \right)^{\text{total}} \cdot g(\epsilon_s^u) \cdot \frac{1 - p}{\lambda} \left(\frac{\lambda}{f} b - s_{stw}(\bar{h} - h_{stw}(\epsilon_s^u)) \right) \\
& + \left(\frac{\partial \xi_s^c}{\partial \theta} \right)^{\text{total}} \cdot g(\xi_s^c) \cdot \frac{p}{\lambda} \cdot \frac{\lambda}{f} b \cdot \mathbb{1}(\epsilon_{stw} \leq \xi_s^c) \\
& + \left(\frac{\partial \epsilon_s^c}{\partial \theta} \right)^{\text{total}} \cdot g(\epsilon_s^c) \cdot \frac{p}{\lambda} \left(\frac{\lambda}{f} b - s_{stw}(\bar{h} - h_{stw}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{stw} \geq \epsilon_s^c) \\
& + \left(\frac{\partial c^w}{\partial \theta} \right)^{\text{total}} \cdot \left(-\frac{\partial S}{\partial c^w} \right)^{\text{total}} \\
& + \tilde{I} E_\theta
\end{aligned}$$

Note: $\frac{1}{M}$ denotes the general equilibrium effect of an increase of the joint surplus on θ :

$$\left(\frac{\partial \theta}{\partial S} \right)^{\text{ge}} = \frac{1}{M}$$

Rearranging for λ_θ gives:

$$\begin{aligned}
M \cdot \lambda_\theta = & \\
& u'(c^w) \cdot \left(\frac{\partial f}{\partial S} \right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \frac{\lambda}{f} \cdot b \right) \\
& + u'(c^w) \cdot n^s \cdot \left(\left(-\frac{\partial \epsilon_s^u}{\partial S} \right)^{\text{ge}} \cdot g(\epsilon_s^u) \cdot \frac{1 - p}{\lambda} \left(\frac{\lambda}{f} \cdot b - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u)) \right) \right) \\
& + u'(c^w) \cdot n^s \cdot \left(\left(-\frac{\partial \xi_s^c}{\partial S} \right)^{\text{ge}} \cdot g(\xi_s^c) \cdot \frac{p}{\lambda} \cdot \frac{\lambda}{f} \cdot b \cdot \mathbb{1}(\epsilon_{stw} \leq \xi_s^c) \right) \\
& + u'(c^w) \cdot n^s \\
& \cdot \left(\left(-\frac{\partial \epsilon_s^c}{\partial S} \right)^{\text{ge}} \cdot g(\epsilon_s^c) \cdot \frac{p}{\lambda} \cdot \left(\frac{\lambda}{f} \cdot b - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{stw} \geq \epsilon_s^c) \right) \\
& + u'(c^w) \cdot n^s \cdot \left(\frac{\partial \theta}{\partial S} \right)^{\text{ge}} \cdot \tilde{I}E_\theta
\end{aligned}$$

Define:

$$\begin{aligned}
\hat{I}E_\theta = & \frac{1}{1 - \rho^c} \cdot \left[\int_{\max\{\epsilon_{stw}, \xi_s^c\}}^{\epsilon^p} \lambda \cdot \frac{\gamma}{f} \cdot \frac{u'(c^w(\epsilon)) - u'(c^w)}{u'(c^w)} dG(\epsilon) \right. \\
& \left. - \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \xi_s^c\}} \lambda \cdot \frac{\gamma}{f} \cdot \frac{u'(c_{stw}(\epsilon)) - u'(c^w)}{u'(c^w)} dG(\epsilon) \right] \cdot k_v
\end{aligned}$$

Note:

$$\begin{aligned}
\left(\frac{\partial f}{\partial S} \right)^{\text{ge}} &= \frac{1}{M} \cdot \frac{\partial f}{\partial S} \\
\left(\frac{\partial \epsilon_s^u}{\partial S} \right)^{\text{ge}} &= \frac{1}{M} \cdot \left(\frac{\partial \epsilon_s^u}{\partial S} \right)^{\text{total}} \\
\left(\frac{\partial \xi_s^c}{\partial S} \right)^{\text{ge}} &= \frac{1}{M} \cdot \left(\frac{\partial \xi_s^c}{\partial S} \right)^{\text{total}} \\
\left(\frac{\partial \epsilon_s^c}{\partial S} \right)^{\text{ge}} &= \frac{1}{M} \cdot \left(\frac{\partial \epsilon_s^c}{\partial S} \right)^{\text{total}}
\end{aligned}$$

Further, note that:

$$\begin{aligned}
\frac{\partial n^u}{\partial \epsilon_s^u} &= -g(\epsilon_s^u) \cdot \frac{1 - p}{\lambda} \cdot n^s \\
\frac{\partial n^c}{\partial \epsilon_s^c} &= -g(\epsilon_s^c) \cdot \frac{1 - p}{\lambda} \cdot n^s \\
\frac{\partial n^c}{\partial \xi_s^c} &= -g(\xi_s^c) \cdot \frac{1 - p}{\lambda} \cdot n^s
\end{aligned}$$

This gives:

$$\begin{aligned}
\lambda_c = & -\frac{1}{\left(\frac{\partial WE}{\partial c^w}\right)^{\text{total}}} \left[\left(\frac{\partial \epsilon_s^u}{\partial c^w} + \left(\frac{\partial S}{\partial c^w} \right)^{\text{total}} \left(\frac{\partial \epsilon_s^u}{\partial S} \right)^{\text{ge}} \right) \right. \\
& \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) \cdot u'(c^w) \left(\frac{\lambda}{f} b - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^u)) \right) \\
& + \left(\frac{\partial \xi_s^c}{\partial c^w} + \left(\frac{\partial S}{\partial c^w} \right)^{\text{total}} \left(\frac{\partial \xi_s^c}{\partial S} \right)^{\text{ge}} \right) \\
& \cdot \left(-\frac{\partial n^c}{\partial \xi_s^c} \right) \cdot u'(c^w) \cdot \frac{\lambda}{f} b \cdot \mathbb{1}(\epsilon_{\text{stw}} \leq \xi_s^c) \\
& + \left(\frac{\partial \epsilon_s^c}{\partial c^w} + \left(\frac{\partial S}{\partial c^w} \right)^{\text{total}} \left(\frac{\partial \epsilon_s^c}{\partial S} \right)^{\text{ge}} \right) \\
& \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot u'(c^w) \left(\frac{\lambda}{f} b - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c) \\
& + \left(\frac{\partial S}{\partial c^w} \right)^{\text{total}} \left(\frac{\partial f}{\partial S} \right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \left(1 + \frac{\lambda_\theta}{n^s u'(c^w)} \right) \cdot \frac{b}{f} \right) \\
& \left. - n^c \cdot \left(\frac{\partial S}{\partial c^w} \right)^{\text{total}} \left(\frac{\partial \theta}{\partial S} \right)^{\text{ge}} \cdot I\hat{E}_\theta \right]
\end{aligned}$$

Following the same arguments, we can express the Lagrange multiplier for the separation conditions as:

$$\begin{aligned}
\lambda_{\epsilon_s^u} = & -\frac{u'(c^w)}{\left(\frac{\partial S_{\text{stw}}^u(\epsilon_s^u)}{\partial \epsilon_s^u}\right)^{\text{total}}} \left[\left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right)^{\text{ge}} \cdot \left(\frac{\lambda}{f} \cdot b - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^u)) \right) \right. \\
& + \left(\frac{\partial \xi_s^c}{\partial \epsilon_s^u} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \xi_s^c} \right) \cdot \frac{\lambda}{f} \cdot b \cdot \mathbb{1}(\epsilon_{\text{stw}} \leq \xi_s^c) \\
& + \left(\frac{\partial \epsilon_s^c}{\partial \epsilon_s^u} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \left(\frac{\lambda}{f} b - s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c) \\
& + \frac{\partial c^w}{\partial \epsilon_s^u} \left(\frac{\partial f}{\partial c^w} \right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \frac{b}{f} \right) \\
& \left. + n^c \cdot \frac{\partial c^w}{\partial \epsilon_s^u} \left(\frac{\partial \theta}{\partial c^w} \right)^{\text{ge}} \cdot I\hat{E}_\theta \right].
\end{aligned}$$

$$\begin{aligned}
\lambda_{\xi_s^c} = & -\frac{u'(c^w)}{\left(\frac{\partial S_{stw}^c(\xi_s^c)}{\partial \xi_s^c}\right)^{\text{total}}} \left[\left(\frac{\partial \xi_s^u}{\partial \xi_s^c} \right)^{\text{ge}} \cdot \frac{\partial n^c}{\partial \xi_s^c} \left(\frac{\lambda}{f} b - s_{stw}(\bar{h} - h_{stw}(\xi_s^u)) \right) \right. \\
& + \left(-\frac{\partial n^c}{\partial \xi_s^c} \right)^{\text{ge}} \cdot \frac{\lambda}{f} b \cdot \mathbb{1}(\epsilon_{stw} \leq \xi_s^c) \\
& + \left(\frac{\partial \xi_s^c}{\partial \xi_s^c} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \xi_s^c} \right) \left(\frac{\lambda}{f} b - s_{stw}(\bar{h} - h_{stw}(\xi_s^c)) \right) \cdot \mathbb{1}(\epsilon_{stw} \geq \xi_s^c) \\
& + \frac{\partial c^w}{\partial \xi_s^c} \left(\frac{\partial f}{\partial c^w} \right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \frac{b}{f} \right) \\
& \left. + n^c \cdot \frac{\partial c^w}{\partial \xi_s^c} \left(\frac{\partial \theta}{\partial c^w} \right)^{\text{ge}} \cdot \hat{I}E_\theta \right]
\end{aligned}$$

$$\begin{aligned}
\lambda_{\epsilon_s^c} = & -\frac{u'(c^w)}{\left(\frac{\partial S_{stw}^c(\epsilon_s^c)}{\partial \epsilon_s^c}\right)^{\text{total}}} \left[\left(\frac{\partial \epsilon_s^u}{\partial \epsilon_s^c} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^c} \right) \left(\frac{\lambda}{f} b - s_{stw}(\bar{h} - h_{stw}(\xi_s^u)) \right) \right. \\
& + \left(\frac{\partial \xi_s^c}{\partial \epsilon_s^c} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot \frac{\lambda}{f} b \cdot \mathbb{1}(\epsilon_{stw} \leq \epsilon_s^c) \\
& + \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \left(\frac{\lambda}{f} b - s_{stw}(\bar{h} - h_{stw}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{stw} \geq \epsilon_s^c) \\
& + \frac{\partial c^w}{\partial \epsilon_s^c} \left(\frac{\partial f}{\partial c^w} \right)^{\text{ge}} \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \frac{b}{f} \right) \\
& \left. + n^c \cdot \frac{\partial c^w}{\partial \epsilon_s^c} \left(\frac{\partial \theta}{\partial c^w} \right)^{\text{ge}} \cdot \hat{I}E_\theta \right]
\end{aligned}$$

For convenience, the optimal UI benefits are reproduced here:

$$\begin{aligned}
(1 - \eta) \cdot (u'(b) - u'(c^w)) = & \lambda_\theta (1 - \rho) \cdot \left(\frac{1 - n}{n} + \frac{u'(b)}{u'(c^w)} \right) \\
& + (\lambda_{\epsilon_s^u} + \lambda_{\xi_s^c} + \lambda_{\epsilon_s^c}) \cdot \left(-\frac{u'(b)}{u'(c^w)} \right) \\
& + \lambda_c \cdot (1 - \rho) \cdot \left(\eta \cdot \frac{1 - n}{n} - (1 - \eta) \cdot \frac{u'(b)}{u'(c^w)} \right)
\end{aligned}$$

Inserting the Lagrange multiplier gives:

$$\begin{aligned}
& (1 - n)(u'(b) - u'(c^w)) \\
&= u'(c^w) \left[\left(\frac{\partial c^w}{\partial b} \right)^{\text{ge}} \left(-\frac{\partial f}{\partial c^w} \right) \cdot u \cdot \left(\frac{\eta - \gamma}{(1 - \gamma)(1 - \eta)} \cdot \frac{k_v}{q} + \frac{b}{f} \right) \right. \\
&\quad + \left(\frac{\partial \epsilon_s^u}{\partial b} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) \cdot \left(\frac{\lambda}{f} \cdot b - s_{stw} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^u)) \right) \\
&\quad + \left(\frac{\partial \xi_s^c}{\partial b} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \xi_s^c} \right) \cdot \frac{\lambda}{f} \cdot b \cdot \mathbb{1}(\epsilon_{\text{stw}} \leq \xi_s^c) \\
&\quad + \left(\frac{\partial \epsilon_s^c}{\partial b} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot \left(\frac{\lambda}{f} \cdot b - s_{stw} \cdot (\bar{h} - h_{\text{stw}}(\epsilon_s^c)) \right) \cdot \mathbb{1}(\epsilon_{\text{stw}} \geq \epsilon_s^c) \\
&\quad \left. + n^c \left(-\frac{\partial \theta}{\partial b} \right)^{\text{ge}} \cdot I \hat{E}_\theta \right]
\end{aligned}$$

with

$$\begin{aligned}
& \left(\frac{\partial \epsilon_s^u}{\partial b} \right)^{\text{ge}} \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) = \underbrace{\left(\frac{\partial \epsilon_s^u}{\partial b} \right)^{\text{ge}} \left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right)}_{\text{direct effects}} \\
& + \underbrace{\left[\frac{\partial S}{\partial b} \left(\frac{\partial \epsilon_s^u}{\partial S} \right)^{\text{ge}} + \frac{\partial \xi_s^c}{\partial b} \left(\frac{\partial c^w}{\partial \xi_s^c} \right)^{\text{ge}} + \frac{\partial \epsilon_s^c}{\partial b} \left(\frac{\partial c^w}{\partial \epsilon_s^c} \right)^{\text{ge}} + \frac{\partial c^w}{\partial b} \left(\frac{\partial \epsilon_s^u}{\partial c^w} \right)^{\text{ge}} \right]}_{\text{indirect effect}} \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right)
\end{aligned}$$

$$\begin{aligned}

\end{aligned}$$

K Proof of Lemma 1

Separation condition: unconstrained matches

$$z_{\text{stw}}(\epsilon_s^u) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + s_{\text{stw}}(\bar{h} - h(\epsilon_s^u)) + \frac{\lambda - \eta \cdot f}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

Separation condition: constrained matches

$$\frac{u(c_{\text{stw}}(\epsilon_s^c)) - u(b)}{u'(c^w)} + \frac{\eta}{1 - \eta} \cdot (\lambda - f) \cdot \frac{k_v}{q}$$

Remember:

$$c_{\text{stw}}(\epsilon) = z_{\text{stw}}(\epsilon_s^c) + s_{\text{stw}}(\bar{h} - h(\epsilon_s^c)) + \lambda \cdot \frac{k_v}{q}$$

This allows us to rewrite the separation condition of constrained firms on STW as:

$$z_{\text{stw}}(\epsilon_s^c) + \frac{u(c_{\text{stw}}(\epsilon_s^c)) - u(b)}{u'(c^w)} - c_{\text{stw}}(\epsilon_s^c) + s_{\text{stw}}(\bar{h} - h(\epsilon_s^c)) + \frac{\lambda - \eta \cdot f}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

T.b.s.: $\epsilon_s^c > \epsilon_s^u$ (the proof for $\xi_s^c > \xi_s^u$ is completely analogous)

Note: $c^w > c_{\text{stw}}(\epsilon)$

$$\begin{aligned} \epsilon_s^c > \epsilon_s^u &\Leftrightarrow z_{\text{stw}}(\epsilon) + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + s_{\text{stw}}(\bar{h} - h(\epsilon)) \\ &\quad + \frac{\lambda - \eta f}{1 - \eta} \cdot \frac{k_v}{q} \\ &\geq z_{\text{stw}}(\epsilon) + \frac{u(c_{\text{stw}}(\epsilon)) - u(b)}{u'(c^w)} - c_{\text{stw}}(\epsilon) \\ &\quad + s_{\text{stw}}(\bar{h} - h(\epsilon)) + \frac{\lambda - \eta f}{1 - \eta} \cdot \frac{k_v}{q} \end{aligned}$$

$$\Leftrightarrow \frac{u(c^w)}{u'(c^w)} - c^w > \frac{u(c_{\text{stw}}(\epsilon))}{u'(c^w)} - c_{\text{stw}}(\epsilon)$$

$$\Leftrightarrow \frac{u(c^w) - u(c_{\text{stw}}(\epsilon))}{u'(c^w)} > c^w - c_{\text{stw}}(\epsilon)$$

$$\Leftrightarrow u(c^w) - u(c_{\text{stw}}(\epsilon)) > (c^w - c_{\text{stw}}(\epsilon)) \cdot u'(c^w)$$

$$\Leftrightarrow \int_{c_{\text{stw}}(\epsilon)}^{c^w} u'(c) dc > \int_{c_{\text{stw}}(\epsilon)}^{c^w} u'(c^w) dc$$

$$\Leftrightarrow \int_{c_{\text{stw}}(\epsilon)}^{c^w} [u'(c) - u'(c^w)] dc > 0 \quad \checkmark \quad (\text{due to risk aversion})$$

L Calibration

To calibrate the model, the following system of equations can be solved, taking targets as exogenous. The endogenous model variables used in the system are pinned down at

equilibrium level as well. Note that we use $\beta = 1$.

Exogenous:

$$f, q, \rho, b_{\text{rep}}, n$$

Endogenous:

$$k_f, \bar{m}, b, \epsilon_s^c, \epsilon_s^u, c^w, \omega$$

(I)

$$\rho = (1 - p) \cdot G(\epsilon_s^u) + p \cdot G(\epsilon_s^c)$$

(II)

$$0 = z(\epsilon_s^u) + \lambda \cdot F + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + \frac{\lambda - \eta f}{1 - \eta} \cdot \frac{k_v}{q}$$

(III)

$$0 = z(\epsilon_p) + \lambda \cdot \frac{k_v}{q} - c^w$$

(IV)

$$\frac{u(c(\epsilon_s^u)) - u(b)}{u'(c^w)} + (\lambda - f) \cdot \frac{\eta}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

(V)

$$\begin{aligned} \frac{1}{1 - \eta} \cdot \frac{k_v}{q} = \frac{1}{\lambda} & \left[(1 - \rho) \cdot \left(z - \frac{1 - \eta}{\eta} b \right) \right. \\ & + (1 - p)(1 - \rho^u) \cdot \left(\frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right) \\ & + p(1 - \rho^c) \cdot \left(\frac{u(c^c) - u(b)}{u'(c^w)} - e^c \right) \\ & \left. + (1 - \rho) \cdot \frac{\lambda - f\eta}{1 - \eta} \cdot \frac{k_v}{q} \right] \end{aligned}$$

(VI)

$$\begin{aligned}
& (1-p) \cdot (1-\rho^u) \cdot \left(\eta \cdot c^w + (1-\eta) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \right) \\
&= \eta \cdot (1-\rho) \cdot \left(z + \frac{1-n}{n} \cdot b + \theta \cdot k_v \right) \\
&\quad - p \cdot (1-\rho^c) \cdot \left[(1-\eta) \cdot \frac{u^c - u(b)}{u'(c^w)} + \eta \cdot e^c \right]
\end{aligned}$$

(VII)

$$\begin{aligned}
\omega = \frac{1}{1-\rho} \cdot & \left((1-p) \cdot \int_{\epsilon_s^u}^{\infty} [c^w + \phi(h(\epsilon))] dG(\epsilon) \right. \\
& + p \cdot \int_{\epsilon_p}^{\infty} [c^w + \phi(h(\epsilon))] dG(\epsilon) \\
& \left. + p \cdot \int_{\epsilon_s^c}^{\epsilon_p} [c(\epsilon) + \phi(h(\epsilon))] dG(\epsilon) \right)
\end{aligned}$$

(VIII)

$$b = b_{\text{rep}} \cdot \omega$$

M Optimization

To optimize for policy parameters, we use the following algorithm: First we use the global Covariance Matrix Adaptation Evolution Strategy (CMA-ES) with 8 random starting points. Then we select the best 4 solutions and use a local trust region optimization algorithm to further optimize these candidates. As the local optimization algorithm we rely on BOBYQA (Bound Optimization BY Quadratic Approximation). Finally, we select the best solution among these 4 candidates as the optimal policy parameters. This procedure is conducted independently for each value of p . Note, that since the Ramsey planner must obey the equilibrium conditions, each welfare evaluation of welfare within these optimization algorithms requires solving the model for the given policy parameters. We rely on an evenly spaced grid for p of 96 points between 0 and 1.

N Joint Optimal Design of STW and Lay-off Taxes

N.1 Ramsey Problem

For $\beta \rightarrow 1$ the Ramsey planner's problem reads:

$$\begin{aligned} \max_{b, s_{stw}, \epsilon_{stw}} \quad & n^u \cdot u(c^w) + n^c \cdot u^c + (1 - n) \cdot u(b) \\ & + v^f \cdot u((n \cdot (z - \Omega) - n^u \cdot c^w - n^c \cdot e^c - \tau(b) - \theta \cdot (1 - n) \cdot k_v) / v^f) \end{aligned}$$

subject to the following constraints:

(I) Number of unconstrained workers:

$$n^u = \frac{1 - p}{\lambda} \cdot (1 - \rho^u) \cdot n^s$$

(II) Separation rate (unconstrained workers):

$$\rho^u = G(\epsilon_s^u)$$

(III) Number of constrained workers:

$$n^c = \frac{p}{\lambda} \cdot (1 - \rho^c) \cdot n^s$$

(IV) Separation rate (constrained workers):

$$\rho^c = G(\max\{\xi_s^c, \epsilon_{stw}\}) - G(\max\{\epsilon_{stw}, \epsilon_s^c\}) + G(\xi_s^c)$$

(V) Aggregate separation rate:

$$\rho = (1 - p) \cdot \rho^u + p \cdot \rho^c$$

(VI) Number of firms that are hit by a shock:

$$n^s = \theta \cdot q(\theta) \cdot (1 - n) + \lambda \cdot n$$

(VII) Total employment:

$$n = n^u + n^c$$

(VIII) Average utility of a constrained worker:

$$u^c = \frac{1}{1 - \rho^c} \left((1 - G(\epsilon^p)) \cdot u(c^w) + \int_{\max\{\epsilon_{stw}, \xi_s^c\}}^{\epsilon^p} u(c^w(\epsilon)) dG(\epsilon) + \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} u(c_{stw}^w(\epsilon)) dG(\epsilon) \right)$$

(IX) Average cost of a constrained worker for a firm:

$$e^c = \frac{1}{1 - \rho^c} \left[(1 - G(\epsilon^p)) \cdot c^w + \int_{\max\{\epsilon_{stw}, \xi_s^c\}}^{\epsilon^p} c^w(\epsilon) dG(\epsilon) + \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} (c_{stw}^w(\epsilon) - s_{stw}(\bar{h} - h_{stw}(\epsilon))) dG(\epsilon) \right]$$

(X) Average production (without distortions):

$$z = \frac{1}{1 - \rho} \left((1 - p) \int_{\xi_s^u}^{\infty} z(\epsilon) dG(\epsilon) + p \int_{\max\{\xi_s^c, \epsilon_{stw}\}}^{\infty} z(\epsilon) dG(\epsilon) + p \cdot \int_{\epsilon_s^c}^{\max\{\epsilon_s^c, \epsilon_{stw}\}} z(\epsilon) dG(\epsilon) \right)$$

(XI) Average distortion of working hours:

$$\Omega = \frac{1}{1 - \rho} \left((1 - p) \int_{\epsilon_s^u}^{\epsilon_{stw}} \Omega(\epsilon) dG(\epsilon) + p \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} \Omega(\epsilon) dG(\epsilon) \right)$$

with $\Omega(\epsilon) = \bar{z}(\epsilon) - z_{stw}(\epsilon)$

(XII) Job-creation condition:

$$\begin{aligned} \frac{1}{1 - \eta} \cdot \frac{k_v}{q} = \frac{1}{\lambda} & \left[(1 - \rho) \left(z - \Omega - \frac{1 - n}{n} b \right) \right. \\ & + p(1 - \rho^u) \left(\frac{u(c^w) - u(b)}{u'(c^w)} - c^w \right) \\ & + (1 - p)(1 - \rho^c) \left(\frac{u^c - u(b)}{u'(c^w)} - e^c \right) \\ & \left. + (1 - \rho) \cdot \frac{\lambda - \eta \cdot f}{1 - \eta} \cdot \frac{k_v}{q} \right] \end{aligned}$$

(XIII) Wage:

$$\begin{aligned}
WE = (1-p) \cdot (1-\rho^u) & \left(\eta \cdot c^w + (1-\eta) \cdot \frac{u(c^w) - u(b)}{u'(c^w)} \right) \\
& - \eta(1-\rho) \left(z - \Omega - \frac{1-n}{n}b + \theta \cdot k_v \right) \\
& + p \cdot (1-\rho^c) \left[(1-\eta) \cdot \frac{u^c - u(b)}{u'(c^w)} + \eta \cdot e^c \right] = 0
\end{aligned}$$

(XIV) Separation condition for unconstrained firm without STW:

$$z(\xi_s^u) + \lambda \cdot F + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + \frac{\lambda - \eta \cdot f}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

(XV) Separation condition for unconstrained firm with STW:

$$z_{\text{stw}}(\epsilon_s^u) + s_{\text{stw}}(\bar{h} - h_{\text{stw}}(\epsilon_s^u)) + \lambda \cdot F + \frac{u(c^w) - u(b)}{u'(c^w)} - c^w + \frac{\lambda - \eta \cdot f}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

(XVI) Threshold at which the constraint is binding:

$$z(\epsilon_p) + \lambda \cdot \frac{k_v}{q} = c^w$$

(XVII) Separation condition, constrained firm without STW:

$$\frac{u(c^w(\xi_s^c)) - u(b)}{u'(c^w)} + (\lambda - f) \cdot \frac{\eta}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

(XVIII) Separation condition, constrained firm with STW:

$$\frac{u(c_{\text{stw}}^w(\epsilon_s^c))}{u'(c^w)} + (\lambda - f) \cdot \frac{\eta}{1 - \eta} \cdot \frac{k_v}{q} = 0$$

(XIX) Consumption, constrained worker outside STW

$$c^w(\epsilon) = z(\epsilon) + \lambda \cdot \frac{k_v}{q}$$

(XX) Consumption, constrained worker on STW

$$c_{stw}^w(\epsilon) = z_{stw}(\epsilon) + s_{stw}(\bar{h} - h_{stw}(\epsilon)) + \lambda \cdot \frac{k_v}{q}$$

Forming the FOCs for the separation thresholds with and without STW and the FOCs related to labor market tightness and employment we can calculate the Lagrange multipliers for the separation thresholds and express them as:

$$\begin{aligned} -\frac{\lambda_{\xi_s^u}}{n^s \cdot u'(c^w)} &= \mathbb{1}\{\epsilon_{stw} < \xi_s^u\} \cdot \frac{1-p}{\lambda} \cdot g(\xi_s^u) \cdot \frac{1}{\frac{\partial S_{stw}^u(\xi_s^u)}{\partial \xi_s^u}} \cdot \left[\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F\right) \right. \\ &\quad \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\xi_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \xi_s^c}\right) \right] \\ -\frac{\lambda_{\epsilon_s^u}}{n^s \cdot u'(c^w)} &= \mathbb{1}\{\epsilon_{stw} \geq \epsilon_s^u\} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot \frac{1}{\frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial \epsilon_s^u}} \\ &\quad \cdot \left[\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u))\right) \right. \\ &\quad \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda}{1-p} \cdot \frac{\partial WE}{\partial \epsilon_s^u}\right) \right] \\ -\frac{\lambda_{\epsilon_s^c}}{n^s \cdot u'(c^w)} &= \mathbb{1}\{\epsilon_{stw} \geq \epsilon_s^c\} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot \frac{1}{\frac{\partial S_{stw}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \\ &\quad \cdot \left[\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right) \cdot \left(\frac{\lambda}{f} \cdot b - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^c))\right) \right. \\ &\quad \left. + \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \epsilon_s^c}\right) \right] \end{aligned}$$

The optimality condition for the layoff tax shows that the Langrange multiplier of the separation thresholds for the unconstrained firms with and without STW has to add up to 0:

$$\lambda_{\epsilon_s^u} + \lambda_{\xi_s^c} = 0$$

The FOC for the STW benefits gives:

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial s_{stw}} &= \frac{p}{\lambda} \cdot n^s \cdot \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} (u'(c_{stw}(\epsilon)) - u'(c^w)) (\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
&+ \lambda_\theta \cdot \frac{p}{\lambda} \cdot \int_{\epsilon_s^c}^{\max\{\epsilon_{stw}, \epsilon_s^c\}} \left(\frac{u'(c_{stw}(\epsilon)) - u'(c^w)}{u'(c^w)} \right) (\bar{h} - h_{stw}(\epsilon)) dG(\epsilon) \\
&- \frac{n^s \cdot (1 - \rho)}{\lambda} \cdot u'(c^w) \cdot \frac{\partial \Omega}{\partial s_{stw}} - \lambda_\theta \cdot \frac{(1 - \rho)}{\lambda} \cdot \frac{\partial \Omega}{\partial s_{stw}} - \lambda_c \cdot \frac{\partial WE}{\partial s_{stw}} \\
&- \lambda_{\epsilon_s^u} \cdot \frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial s_{stw}} - \lambda_{\epsilon_s^c} \cdot \frac{\partial S_{stw}^c(\epsilon_s^c)}{\partial s_{stw}} = 0
\end{aligned}$$

Rearranging gives:

$$MIE_{stw} - MWL_{stw} - \frac{\partial WE}{\partial s_{stw}} \cdot \lambda_c = \lambda_{\epsilon_s^u} \cdot \frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial s_{stw}} + \lambda_{\epsilon_s^c} \cdot \frac{\partial S_{stw}^c(\epsilon_s^c)}{\partial s_{stw}}$$

For the subsequent paragraphs let us introduce the following notation:

$$\begin{aligned}
\mathbb{1}\{\epsilon_{stw} < \xi_s^u\} \cdot \left(-\frac{\partial n^u}{\partial \xi_s^u} \right) &= \mathbb{1}\{\epsilon_{stw} < \xi_s^u\} \cdot \frac{1-p}{\lambda} \cdot g(\xi_s^u) \cdot n^s \cdot \frac{1}{\frac{\partial S_{stw}^u(\xi_s^u)}{\partial \xi_s^u}} \\
\mathbb{1}\{\epsilon_{stw} \geq \epsilon_s^u\} \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) &= \mathbb{1}\{\epsilon_{stw} \geq \epsilon_s^u\} \cdot \frac{1-p}{\lambda} \cdot g(\epsilon_s^u) \cdot n^s \cdot \frac{1}{\frac{\partial S_{stw}^u(\epsilon_s^u)}{\partial \epsilon_s^u}} \\
\mathbb{1}\{\epsilon_{stw} \geq \epsilon_s^c\} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) &= \mathbb{1}\{\epsilon_{stw} \geq \epsilon_s^c\} \cdot \frac{p}{\lambda} \cdot g(\epsilon_s^c) \cdot n^s \cdot \frac{1}{\frac{\partial S_{stw}^c(\epsilon_s^c)}{\partial \epsilon_s^c}} \\
BE_\xi^u &= \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\xi_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \xi_s^c} \right) \\
BE_\epsilon^u &= \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^u)} \cdot \frac{\lambda}{1-p} \cdot \frac{\partial WE}{\partial \epsilon_s^u} \right) \\
BE_\epsilon^c &= \frac{\lambda_c}{n^s \cdot u'(c^w)} \cdot \left(\eta \cdot \frac{b}{n} + \frac{1}{g(\epsilon_s^c)} \cdot \frac{\lambda}{p} \cdot \frac{\partial WE}{\partial \epsilon_s^c} \right)
\end{aligned}$$

Insert the Lagrange multiplier of the separation conditions of unconstrained firms with and without STW into the optimality condition for the lay-off tax:

$$\begin{aligned}
&\mathbb{1}\{\epsilon_{stw} < \xi_s^u\} \cdot \left(-\frac{\partial n^u}{\partial \xi_s^u} \right) \cdot \left[\left(1 + \frac{\lambda_\theta}{n^u \cdot u'(c^w)} \right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F \right) + BE_\xi^u \right] \\
&+ \mathbb{1}\{\epsilon_{stw} \geq \epsilon_s^u\} \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u} \right) \cdot \left[\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u)) \right) + BE_\epsilon^u \right] \\
&+ \mathbb{1}\{\epsilon_{stw} \geq \epsilon_s^c\} \cdot \left(-\frac{\partial n^c}{\partial \epsilon_s^c} \right) \cdot \left[\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)} \right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^c)) \right) + BE_\epsilon^c \right] = 0
\end{aligned}$$

Rearranging gives formula for optimal lay-off taxes:

$$F = T_{UI} \cdot b - (1 - \omega^\xi) \cdot T_{stw} \cdot s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^c)) + BE_F$$

with

$$BE_F = \omega^\xi \cdot \frac{BE_\xi^u}{\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right)} + (1 - \omega^\xi) \cdot \frac{BE_\epsilon^u}{\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right)}$$

$$\omega^\xi = \frac{\mathbb{1}\{\epsilon_{stw} < \xi_s^u\} \cdot \left(-\frac{\partial n^u}{\partial \xi_s^u}\right)}{\mathbb{1}\{\epsilon_{stw} < \xi_s^u\} \cdot \left(-\frac{\partial n^u}{\partial \xi_s^u}\right) + \mathbb{1}\{\epsilon_{stw} \geq \epsilon_s^u\} \cdot \left(-\frac{\partial n^u}{\partial \epsilon_s^u}\right)}$$

Next, substitute the Lagrange multipliers of the separation conditions with STW for constrained and unconstrained firms into the first-order condition for STW benefits:

$$MIE_{stw}^c - MWL_{stw} - \frac{\partial WE}{\partial s_{stw}} \cdot \lambda_c$$

$$= MMS_{stw}^u \cdot \left[\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right) \cdot \left(\frac{\lambda}{f} \cdot b - \lambda \cdot F - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u))\right) + BE_\epsilon^u \right]$$

$$+ MMS_{stw}^c \cdot \left[\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right) \cdot \left(\frac{\lambda}{f} \cdot b - s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^c))\right) + BE_\epsilon^c \right]$$

Rearrange:

$$\bar{s}_{stw} = \frac{T_{UI}}{T_{stw}} \cdot b - \omega^u \cdot \lambda \cdot F + \frac{MIE_{stw}^c}{MMS_{stw}} - \frac{MWL_{stw}}{MMS_{stw}} + BE_{stw}$$

with

$$\bar{s}_{stw} = \omega^u \cdot s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u)) + (1 - \omega^u) \cdot s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^c))$$

$$BE_{stw} = \omega^u \cdot \frac{BE_\epsilon^u}{\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right)} + (1 - \omega^u) \cdot \frac{BE_\epsilon^c}{\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right)} + \lambda_c \cdot \frac{\partial WE}{\partial s_{stw}}$$

$$\omega^u = \frac{MMS_{stw}^u}{MMS_{stw}}$$

$$MMS_{stw} = MMS_{stw}^u + MMS_{stw}^c$$

Proof Corollary 4 (i) Suppose that all constrained firms at the brink of separation are allowed to enter STW. That is $\epsilon_{stw} \geq \xi_s^c$. This also implies that all unconstrained firms are able to enter STW so that no worker without access to STW is separated so that $\omega^\xi = 0$. This simplifies the expression of the optimal lay-off tax to:

$$F = T_{UI} \cdot b - T_{stw} \cdot s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^c)) + BE_F$$

We can now insert this expression into the expression for the optimal STW benefits:

$$\begin{aligned}\bar{s}_{stw} = & (1 - \omega^u) \cdot \frac{T_{UI}}{T_{stw}} \cdot b + \omega^u \cdot s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u)) + \frac{MIE_{stw}^c}{MMS_{stw}} - \frac{MWL_{stw}}{MMS_{stw}} \\ & + (1 - \omega^u) \cdot \frac{BE_\epsilon^c}{\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right)} + \lambda_c \cdot \frac{\partial WE}{\partial s_{stw}}\end{aligned}$$

Rearranging gives:

$$\begin{aligned}s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^c)) = & \frac{T_{UI}}{T_{stw}} \cdot b + \frac{1}{1 - \omega^u} \cdot \left(\frac{MIE_{stw}^c}{MMS_{stw}} - \frac{MWL_{stw}}{MMS_{stw}} \right) \\ & + \frac{BE_\epsilon^c}{\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right)} + \frac{\lambda_c}{1 - \omega^u} \cdot \frac{\partial WE}{\partial s_{stw}}\end{aligned}$$

Define:

$$BE'_{stw} = \frac{BE_\epsilon^c}{\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right)} + \frac{\lambda_c}{1 - \omega^u} \cdot \frac{\partial WE}{\partial s_{stw}}$$

Further, note that for $p \rightarrow 0$ we must get $\omega^u \rightarrow 1$. Rearranging the formula above then gives

$$\left(\frac{MWL_{stw}}{MMS_{stw}} \right) + \lambda_c \cdot \frac{\partial WE}{\partial s_{stw}} = 0$$

as $MIE_{stw}^c = 0$ when there exist no constrained firms in the economy. The equation is fulfilled when $s_{stw} = 0$.

(ii) Suppose that the government screens out all constrained firms: $\epsilon_{stw} \leq \epsilon_s^c$. This implies $\epsilon_s \leq \epsilon_s^c$, and therefore $MMS_{stw}^c = 0$, which in turn implies $\omega^u = 0$. Further, it implies that $MIE_{stw}^c = 0$. This simplifies the formula for the optimal STW benefits to:

$$\bar{s}_{stw} = \frac{T_{UI}}{T_{stw}} \cdot b - \lambda \cdot F - \frac{MWL_{stw}}{MMS_{stw}} + BE_{stw}$$

Inserting the optimal lay-off tax gives:

$$\begin{aligned}s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u)) = & (1 - \omega^\xi) \cdot s_{stw} \cdot (\bar{h} - h_{stw}(\epsilon_s^u)) - \frac{MWL_{stw}}{MMS_{stw}} \\ & + BE_\epsilon^u + \lambda_c \cdot \frac{\partial WE}{\partial s_{stw}} - \omega^\xi \cdot \frac{BE_\xi^u}{\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right)} + (1 - \omega^\xi) \cdot \frac{BE_\epsilon^u}{\left(1 + \frac{\lambda_\theta}{n^s \cdot u'(c^w)}\right)}\end{aligned}$$

Guess: $s_{stw} = 0$. This implies $\xi_s^u = \epsilon_s^u$. This implies $\omega^\xi = 0$ and $\frac{\partial WE}{\partial s_{stw}} = 0$. Thus, we get:

$$\frac{MWL_{stw}}{MMS_{stw}} = 0$$

This holds for $s_{stw} = 0$, proving the guess.
